Dear Recipient:

The U.S. Department of Transportation Federal Transit Administration (FTA), Sound Transit (the Central Puget Sound Regional Transit Authority), and Washington State Department of Transportation (WSDOT) have prepared this Final Environmental Impact Statement (Final EIS) on the proposed East Link light rail transit project. This project is part of Sound Transit 2, the Regional Transit System Plan for Central Puget Sound. Sound Transit is the project proponent.

The Final EIS has been prepared pursuant to the National Environmental Policy Act (42 U.S.C 4321 to 4370e) and the State Environmental Policy Act (Ch. 43.21C RCW). It has been prepared to inform the public, agencies and decision makers about the environmental consequences of building and operating the East link extension of the light rail system from downtown Seattle to Mercer Island, Bellevue, and Redmond via Interstate 90. The Final EIS examines project route and station alternatives, including the preferred alternative identified by the Sound Transit Board.

The major choices for the project involve the route of the light rail line and station locations. The Sound Transit Board will consider the Final EIS and other information before selecting the route and station locations. After the Board selects the project to be built, FTA will issue a Record of Decision, which will state FTA's decision on the project and list Sound Transit mitigation commitments to reduce or avoid impacts.

The Final EIS includes a separately bound Executive Summary. Also available are separately bound appendices consisting of conceptual design drawings, technical reports, background materials, and responses to comments. Please see the Fact Sheet of this Final EIS regarding how to obtain these documents.

For additional information about this Final EIS, please contact Kent Hale, Senior Environmental Planner (206) 398-5103 or kent.hale@soundtransit.org.

Sincerely,

James Irish

Abstract

Sound Transit proposes to construct and operate an eastern extension of the Link light rail system providing urban transportation improvements in the Central Puget Sound metropolitan region. The East Link project would connect to the existing light rail system in downtown Seattle and extend the system east to Mercer Island, Bellevue, and Redmond. Alternatives are considered in five geographic segments in this EIS. **Segment A, Interstate 90,** connects downtown Seattle to Mercer Island and South Bellevue via I-90. **Segment B, South Bellevue,** connects I-90 to approximately SE 6th Street along one of three corridors: Bellevue Way, 112th Avenue SE, or the BNSF Railway right-of-way**. Segment C, Downtown Bellevue,** would travel through downtown Bellevue between approximately SE 6th Street and an I-405 crossing at either NE 6th Street or NE 12th Street on either an at-grade, elevated, or tunnel profile. **Segment D, Bel-Red/Overlake,** would travel from the I-405 crossing to the Overlake Transit Center, either through the Bel-Red corridor or along SR 520. **Segment E, Downtown Redmond,** would travel from Overlake Transit Center to Downtown Redmond via the SR 520 corridor until West Lake Sammamish Parkway and then proceed through Downtown Redmond via either Redmond Way or in the former BNSF Railway corridor. Alternatives considered include a No Build Alternative, 24 build alternatives (one in Segment A, six in Segment B, ten in Segment C, four in Segment D, and three in Segment E), the No Build Alternative, and four maintenance facility alternatives (three in Segment D and one in Segment E). Each alternative route includes one to four stations; a total of 19 station alternatives, some with multiple location options, exist in the five segments. Construction is expected to start in 2015, with operation under way between 2022 and 2023. The analysis and impact information in this EIS addresses potential long-term and short-term impacts of transportation; acquisitions, displacements and relocations; land use; economics; social impacts, community facilities, and neighborhoods; visual and aesthetic resources; air quality and greenhouse gas; noise and vibration; ecosystem resources; water resources; energy; geology and soils; hazardous materials; electromagnetic fields; public services; utilities; historic and archaeological resources; and parkland and open space. The analysis also considers issues related to environmental justice, protected park and historic resources, and the cost, funding, and cost-effectiveness of the alternatives.

Fact Sheet

Proposed Action

The Central Puget Sound Regional Transit Authority (Sound Transit) proposes to construct and operate an extension of its electric light rail transit system that would improve transportation connectivity between Seattle, Mercer Island, and the east side of Lake Washington to Bellevue and Redmond. The proposed light rail extension, known as the East Link Light Rail Transit Project (East Link Project), would cross Lake Washington in the center lanes of Interstate 90 (I-90) and would operate in a dedicated right-of-way between Seattle and Redmond. The East Link Light Rail Transit Project is included in Sound Transit 2: A Mass Transit Guide, The Regional Transit System Plan for Central Puget Sound (ST2), also known as the Mass Transit Expansion proposal, which was approved by the voters in November 2008.

The East Link corridor is approximately 18 miles long and has been divided into five segments along distinct geographic boundaries: Segment A, Interstate 90 (Seattle to Mercer Island and Bellevue via I-90); Segment B, South Bellevue; Segment C, Downtown Bellevue; Segment D, Bel-Red/Overlake (Downtown Bellevue to Overlake Transit Center); and Segment E, Downtown Redmond (Overlake Transit Center to Downtown Redmond). Alternatives considered include 24 build alternatives (one in Segment A, six in Segment B, ten in Segment C, four in Segment D, and three in Segment E), the No Build Alternative, and four maintenance facility alternatives (three in Segment D and one in Segment E). Each alternative route includes one to four stations; a total of 19 station alternatives, some with multiple location options, exist in the five segments. The segment alternatives would be linked to create a complete, operable light rail system that would connect with the Central Link light rail system at the Chinatown/International District Station in downtown Seattle. The East Link Project might be constructed in phases, depending on available funding or other factors. Sound Transit anticipates that any station including and beyond the last station in Segment C could be considered an interim station.

July 15, 2011

Next Actions

Following publication of the Final EIS, the Sound Transit Board of Directors will make a final decision on the route and station locations to be built for the project. Also, after the Final EIS is published, the Federal Transit Administration (FTA) is expected to issue its Record of Decision (ROD) on the project.

Cost and Availability

This Final EIS is available for public review in a variety of formats and locations. The Final EIS is available on the Sound Transit website (www.soundtransit.org/eastlink). The Final EIS is also available on DVD or CD at no cost from Sound Transit. Paper copies of the Final EIS are available for the cost listed below:

- Executive Summary: FREE
- Final EIS: $25.00
- Appendices to Final EIS: $15.00 each
- Conceptual design drawings: $25.00
- Technical background reports: $15.00 each

Copies of the Final EIS and related documents listed above are available for review or purchase at the offices of Sound Transit, Union Station, 401 South Jackson Street, Seattle, Washington 98104. To request any of the documents, please contact Elma Borbe at (206) 398-5445. To review these documents, please call the Sound Transit librarian at (206) 398-5344 during normal business hours (weekdays from 8:00 a.m. to 5:00 p.m.) to arrange an appointment.

Paper copies of the Final EIS documents are also available for review at the following public places:

- Bellevue College Library
- King County Library System
  - Bellevue Regional Library
  - Mercer Island Public Library
  - Redmond Regional Library
- Seattle Public Library branches
  - Downtown Branch
  - International District /Chinatown Branch Library
  - Douglas Truth Branch Library
- University of Washington Library
- Washington State Department of Transportation Library
- Washington State Library

Appeals

Washington State Environmental Policy Act (SEPA) challenges to this Final EIS are governed by Sound Transit Resolution R7-1 and the SEPA rules and regulations (Ch. 43.21C RCW and WAC 197-11-680). Sound Transit Resolution R7-1 is available online at: http://www.soundtransit.org/About-Sound-Transit/Board-of-Directors/Board-archives/Resolutions-archive.xml. (1994-1997 Resolutions)

As provided in Resolution R7-1, appeals of SEPA determinations must be made in writing by filing a letter of appeal and paying the required fee within 14 days following the date the environmental document is issued. Letters of appeal should be addressed to Joni Earl, Chief Executive Officer, Sound Transit, Union Station, 401 South Jackson Street, Seattle, Washington 98104-2826.

For this Final EIS, appeals must be received by Sound Transit on or before 5:00 p.m. on July 29, 2011. Additional details about the appeals process and requirements are set out in Resolution R7-1 and in the SEPA rules and regulations.

Preface

Local, regional, and state agencies have been studying high-capacity transportation alternatives to connect Seattle with the Eastside of King County since the mid-1960s. In 1976, when expansion plans for Interstate 90 (I-90) were stalled, the affected entities of Seattle, Mercer Island, Bellevue, and the Washington State Highway Commission signed a Memorandum Agreement on the Design and Construction of the I-90 bridge, which called for conversion of the center roadway to dedicated transit usage in the future.

In 2004, the Puget Sound Regional Council (PSRC) prepared the *Central Puget Sound Regional High Capacity Transit Corridor Assessment* to establish a basis for more detailed planning studies and environmental analysis. Applying the adopted land use and metropolitan transportation plan, the report found that the cross-lake corridor, connecting the urban centers of Seattle, Bellevue, Overlake and Redmond, had the highest potential for near-term development of high-capacity transit (HCT) alternatives. Sound Transit's updated Long-Range Plan (2006) includes HCT across I-90 serving these urban centers, and the Sound Transit Board has adopted light rail as the mode for this corridor, now referred to as the East Link Project.

Today, much of Central Link is in operation, and Sound Transit is moving forward with the next phase of mass transit improvements in the Puget Sound region, Sound Transit 2 (ST2). ST2 includes construction of the East Link Project, which is an extension of light rail service from Seattle to Mercer Island, Bellevue, and Redmond via I-90. The ST2 plan funds East Link construction to the Overlake Transit Center in Redmond and provides for environmental review and preliminary engineering from Overlake Transit Center to Downtown Redmond.

Sound Transit, together with the Federal Transit Administration (FTA) and Washington State Department of Transportation (WSDOT), have prepared this Final Environmental Impact Statement (EIS) for the East Link Project in compliance with the National Environmental Policy Act (NEPA), and the Washington State Environmental Policy Act (SEPA). This Final EIS does the following:

- Describes the alternatives and their potential impacts

REDMOND
OVERLAKE
BELLEVUE
SEATTLE
MERCER ISLAND

Aerial of East Link Corridor

- Provides environmental information to assist decision-makers in selecting the project to be built
- Identifies measures to avoid and minimize impacts and, when necessary, compensate for adverse impacts
- Considers cumulative impacts as part of the environmental review process
- Provides information for other environmental processes, including compliance with the following:
    - Endangered Species Act
    - Section 106 of the National Historic Preservation Act of 1966
    - Section 4(f) of the Department of Transportation Act of 1966, 49 United States Code (U.S.C.) 303
    - Section 6(f) of the Land and Water Conservation Funds Act
    - Executive Order 12898 – Environmental Justice

The scope of environmental review and the range of alternatives evaluated in the Final EIS respond to the following: public and agency comments received during the public scoping process that began in September 2006; public and agency comments received on the 2008 Draft EIS and the 2010 Supplemental Draft EIS (SDEIS); and feedback from the public and agencies received through community workshops, briefings, stakeholder presentations, and agency coordination meetings held since the environmental review process began.

In order to comply with NEPA and SEPA and to enhance readability, this Final EIS focuses on the most relevant information regarding project definition, potential adverse impacts, and trade-offs among alternatives. The study area for the Final EIS varies by topic and is described within each section of the document, as appropriate. The Final EIS is organized as follows:

The **Executive Summary** is a separately bound condensed version of the overall document that briefly describes the purpose and need for the project, the project's goals and objectives, and the alternatives being considered. It presents the major impacts for each alternative and potential mitigation, reviews the project's financial characteristics, and provides a brief comparison of the different alternatives. The Executive Summary concludes by identifying the major conclusions, areas of uncertainty, and the project's next steps.

Chapter 1, Purpose and Need, describes the project's purpose and need, background, and goals and objectives.

Chapter 2, Alternatives Considered, describes the alternatives that are studied in this Final EIS. It also presents the history of selecting light rail as the mode of transit and identifies the process used to refine the range of potential project alternatives to the set studied in the Final EIS. This chapter provides a review of construction activities and a comparison of cost estimates by alternative. It concludes by explaining the project's planning and decision-making context, including the major steps in the environmental evaluation and project development process.

Chapter 3, Transportation Environment and Consequences, describes the potentially affected existing and future regional and local transportation system and identifies how the project alternatives could affect that system. It then describes potential strategies to reduce or eliminate transportation impacts. The transportation system elements include transit, highways, arterials, local streets, nonmotorized facilities, freight traffic, and navigable waterways.

Chapter 4, Affected Environment and Environmental Consequences, describes the potentially affected environmental conditions (built and natural) in the study area, explains the impacts from construction and operation of the project alternatives, and describes avoidance and minimization measures. Finally, when adverse impacts cannot be avoided, mitigation is identified as appropriate. This chapter includes the following environmental elements:

- Acquisitions, displacements, and relocations
- Land Use
- Economics
- Social impacts, community facilities, and neighborhoods
- Visual and aesthetic resources
- Air quality
- Noise and vibration
- Ecosystem resources (aquatic resources, vegetation and wildlife, and wetlands)
- Water resources
- Energy
- Geology and soils
- Hazardous materials
- Electromagnetic fields
- Public services
- Utilities
- Historic and archaeological resources
- Parklands and open space

Chapter 5, Cumulative Impacts, describes relevant past, present, and reasonably foreseeable actions and projects in or around the project vicinity and the cumulative impact of the proposed alternatives on each element of the environment.

Chapter 6, Alternatives Evaluation, compares the project alternatives in terms of how effectively they meet the project's goals and objectives.

Chapter 7, Comments and Responses, provides a summary of responses to public and agency comments received on the 2008 Draft EIS and the 2010 SDEIS and responses to common public and agency comments.

Appendices A to **K** provide additional details on the project and Final EIS process. **Appendices A** to **E** and **I**, attached to the main volume of the Final EIS, include document support information (references, lists of preparers and recipients, and acronyms and glossary), public involvement and agency coordination documentation, federally required reports on environmental justice and Section 4(f) and 6(f) resources (park and recreation areas, wildlife refuges, historic sites, and any facilities that have received Land and Water Conservation Act funding), and an operating plan summary; **Appendix I** presents the preliminary mitigation measures and environmental commitments that will be implemented for the

Preferred Alternative identified in the Final EIS. **Appendices F, G2,** and **G3** are separately bound technical appendices related to the affected environment and environmental consequences analyses (materials in **Appendix F** are numbered to match their corresponding environmental elements in **Chapter 4**). **Appendix G2** includes list and maps of all potentially affected parcels, and **Appendix G3** includes a list and maps with general locations for documented hazardous materials sites. **Appendix G1** is a separate large-format document containing conceptual design drawings. **Appendix H**, also bound in separate volumes, contains detailed technical reports prepared for transportation, noise and vibration, ecosystems, and historic and archeological resources. **Appendix J**, also bound in four separate volumes, contains copies of public and agency comments received on the 2008 Draft EIS and 2010 SDEIS and responses to those comments. Last, **Appendix K** includes several reports that evaluated various alignment and station configurations in South Bellevue and Downtown Bellevue. This appendix includes studies prepared jointly by Sound Transit and the City of Bellevue, as well as the City of Bellevue's analysis of their B7R option, which includes potential modifications to the B7 alternative.

  4.1.1 Introduction to Resources and Regulatory Requirements 4.1-1
  4.1.2 Affected Environment 4.1-2
  4.1.3 Environmental Impacts 4.1-2
  4.1.4 Eastside Relocation Opportunities 4.1-13
  4.1.5 Sound Transit Acquisition and Relocation Policy Summary 4.1-13
  4.1.6 Potential Mitigation Measures 4.1-14
4.2 Land Use 4.2-1
  4.2.1 Introduction to Resources and Regulatory Requirements 4.2-1
  4.2.2 Affected Environment 4.2-2
  4.2.3 Environmental Impacts 4.2-12
  4.2.4 Potential Mitigation Measures 4.2-25
4.3 Economics 4.3-1
  4.3.1 Introduction to Resources and Regulatory Requirements 4.3-1
  4.3.2 Affected Environment 4.3-1
  4.3.3 Environmental Impacts 4.3-4
  4.3.4 Potential Mitigation Measures 4.3-17

4.4 Social Impacts, Community Facilities, and Neighborhoods 4.4-1
  4.4.1 Introduction to Resources and Regulatory Requirements 4.4-1
  4.4.2 Affected Environment 4.4-1
  4.4.3 Environmental Impacts 4.4-12
  4.4.4 Potential Mitigation Measures 4.4-28
4.5 Visual and Aesthetic Resources 4.5-1
  4.5.1 Introduction to Resources and Regulatory Requirements 4.5-1
  4.5.2 Affected Environment 4.5-1
  4.5.3 Environmental Impacts 4.5-9
  4.5.4 Potential Mitigation Measures 4.5-23
4.6 Air Quality and Greenhouse Gases 4.6-1
  4.6.1 Introduction to Resources and Regulatory Requirements 4.6-1
  4.6.2 Affected Environment 4.6-1
  4.6.3 Air Quality Impacts 4.6-7
  4.6.4 Conformity Determination 4.6-17
  4.6.5 Potential Mitigation Measures 4.6-18
4.7 Noise and Vibration 4.7-1
  4.7.1 Introduction to Resources and Regulatory Requirements 4.7-1
  4.7.2 Affected Environment 4.7-6
  4.7.3 Environmental Impacts 4.7-12
  4.7.4 Station Platform Noise Levels 4.7-36
  4.7.5 Potential Mitigation Measures 4.7-37
4.8 Ecosystem Resources 4.8-1
  4.8.1 Introduction and Regulatory Requirements 4.8-1
  4.8.2 Affected Environment 4.8-1
  4.8.3 Environmental Impacts 4.8-13
  4.8.4 Potential Mitigation Measures 4.8-30
4.9 Water Resources 4.9-1
  4.9.1 Introduction to Resources and Regulatory Requirements 4.9-1
  4.9.2 Affected Environment 4.9-1
  4.9.3 Environmental Impacts 4.9-9
  4.9.4 Potential Mitigation Measures 4.9-20
4.10 Energy Impacts 4.10-1
  4.10.1 Introduction to Resources and Regulatory Requirements 4.10-1
  4.10.2 Affected Environment 4.10-1
  4.10.3 Environmental Impacts 4.10-2
  4.10.4 Potential Mitigation Measures 4.10-5
4.11 Geology and Soils 4.11-1
  4.11.1 Introduction to Resources and Regulatory Requirements 4.11-1
  4.11.2 Affected Environment 4.11-1
  4.11.3 Environmental Impacts 4.11-7
  4.11.4 Potential Mitigation Measures 4.11-18
4.12 Hazardous Materials 4.12-1
  4.12.1 Introduction to Resources and Regulatory Requirements 4.12-1
  4.12.2 Affected Environment 4.12-1
  4.12.3 Environmental Impacts 4.12-3
  4.12.4 Potential Mitigation Measures 4.12-15
4.13 Electromagnetic Fields 4.13-1
  4.13.1 Introduction to Resources and Regulatory Requirements 4.13-1
  4.13.2 Affected Environment 4.13-1
  4.13.3 Environmental Impacts 4.13-2
  4.13.4 Potential Mitigation Measures 4.13-4
4.14 Public Services 4.14-1
  4.14.1 Introduction to Resources and Regulatory Requirements 4.14-1
  4.14.2 Affected Environment 4.14-1

4.14.3 Environmental Impacts 4.14-3
4.14.4 Potential Mitigation Measures....4.14-12
4.15 Utilities 4.15-1
4.15.1 Introduction to Resources and Regulatory Requirements....4.15-1
4.15.2 Affected Environment 4.15-1
4.15.3 Environmental Impacts 4.15-2
4.15.4 Potential Mitigation Measures....4.15-16
4.16 Historic and Archaeological Resources 4.16-1
4.16.1 Introduction to Resources and Regulatory Requirements....4.16-1
4.16.2 Affected Environment 4.16-1
4.16.3 Environmental Impacts 4.16-9
4.16.4 Potential Mitigation Measures....4.16-21
4.17 Parkland and Open Space 4.17-1
4.17.1 Introduction to Resources and Regulatory Requirements....4.17-1
4.17.2 Affected Environment 4.17-1
4.17.3 Environmental Impacts 4.17-3
4.17.4 Potential Mitigation Measures....4.17-22
5 Cumulative Impacts 5-1
5.1 Introduction.... 5-1
5.2 Geographic and Temporal Boundaries of Cumulative Analysis 5-1
5.3 Past and Present Actions 5-2
5.4 Reasonably Foreseeable Future Actions 5-3
5.5 Cumulative Impact Assessment 5-3
5.5.1 Transportation 5-3
5.5.2 Acquisitions, Displacements, and Relocations 5-8
5.5.3 Land Use.... 5-8
5.5.4 Economics.... 5-9
5.5.5 Social Impacts, Community Facilities, and Neighborhoods 5-9
5.5.6 Visual and Aesthetic Resources.... 5-10
5.5.7 Air Quality and Greenhouse Gases 5-10
5.5.8 Noise and Vibration.... 5-12
5.5.9 Ecosystem Resources 5-12
5.5.10 Water Resources 5-13
5.5.11 Energy 5-14
5.5.12 Geology and Soils.... 5-14
5.5.13 Hazardous Materials.... 5-14
5.5.14 Electromagnetic Fields.... 5-14
5.5.15 Public Services 5-15
5.5.16 Utilities.... 5-15
5.5.17 Historic and Archaeological Resources.... 5-15
5.5.18 Parkland and Open Space 5-16
5.5.19 Potential Mitigation Measures for Cumulative Impacts.... 5-16
6 Alternatives Evaluation.... 6-1
6.1 Performance in Meeting Project Goals and Objectives.... 6-1
6.1.1 Transportation Goal: Improving Mobility 6-1
6.1.2 Environmental Goal: Preserve Environmental Quality 6-4
6.1.3 Land Use Goal: Support Regional and Local Land Use Goals and Objectives.... 6-12
6.1.4 Implementation Goal: Minimize Risks.... 6-15
6.1.5 Financial Goal: Achieve Financial Feasibility.... 6-17
6.2 Comparison of Benefits and Environmental Impacts.... 6-21
6.3 Areas of Controversy and Issues to be Resolved 6-22

7 Public and Agency Comment Summary 7-1
7.1 Introduction 7-1
7.2 Overview of Comments Received 7-1
7.2.1 Draft EIS Overview 7-1
7.2.2 SDEIS Overview 7-6
7.3 Comments Received from Public Agencies 7-8
7.3.1 Project Area Jurisdictions 7-8
7.4 Comments Received from Organizations 7-15
7.4.1 Businesses and Business Groups 7-15
7.4.2 Residential Groups 7-18
7.4.3 Interest Groups 7-19
7.5 Responses to Common Comments 7-21
7.6 Review of City of Bellevue B7R Study 7-35
7.6.1 Transportation 7-38
7.6.2 Environmental Consequences 7-39

Tables

1-1 City and King County Population Forecasts
1-2 Employment Forecasts by City
1-3 Expected Growth in Seattle, Bellevue, and Redmond Urban Centers
1-4 Planned New Development

2-1 Components of No Build Alternative
2-2 Characteristics of Light Rail Alternatives
2-3 Characteristics of Stations
2-4 Maintenance Facility Characteristics
2-5 Weekday Service Periods
2-6 Total Costs of Combining Segment B and Segment C Alternatives
2-7 Project Milestones

3-1 Future PM Peak-Hour Traffic Growth Rate for No Build Alternative
3-2 2030 Regional Travel Impact Comparison Summary
3-3 2030 PM Peak-Hour Volume-to-Capacity Ratios at Screenlines
3-4 Existing Transit Facilities in Study Area
3-5 Transit LOS Definitions
3-6 PM Peak-Hour Passenger Load Level of Service at Screenlines
3-7 Transit Reliability Level of Service at Stations
3-8 Comparative Analysis of Year 2030 Average Door-to-Door PM Peak-Period Transit Travel Times
3-9 Year 2030 Daily Ridership Forecasts for the Preferred Alternatives
3-10 Year 2020 and 2030 Daily Ridership Forecast in Segment A
3-11 Year 2020 and 2030 Daily Ridership Forecast in Segment B
3-12 Year 2020 and 2030 Ridership Forecasts in Segment C (connecting from Alternative B3 or B7)
3-13 Year 2020 and 2030 Ridership Forecasts in Segment C (connecting from *Preferred Alternative B2M* or Alternative B2A)
3-14 Year 2020 and 2030 Daily Ridership Forecasts in Segment D
3-15 Year 2020 and 2030 Daily Ridership Forecasts In Segment E
3-16 Year 2020 and 2030 Daily Terminus Station and Projectwide Ridership Forecasts for Interim Terminus Stations
3-17 Existing (2007) I-90 AM and PM Peak-Hour Vehicles and Persons
3-18 I-90 Existing Travel Times by Mode
3-19 Screenline 2 Existing, 2020, and 2030 Mode Share for I-90 and SR 520
3-20 2020 and 2030 Vehicle and Person Peak-Hour Throughput for I-90 at Lake Washington (Screenline 2)
3-21 2020 and 2030 Vehicle and Person Peak-Hour Throughput for I-90 at Mercer Slough (Screenline 3)
3-22 2030 Vehicle and Person Peak-Hour Demand Served for I-90 at Lake Washington (Screenlines 2 and 3)
3-23 2020 and 2030 Travel Times on I-90 between Seattle and I-405 by Mode for No Build Alternative and Light Rail (minutes)
3-24 Intersection Level of Service Standards
3-25 Existing Unrestricted On-Street Parking Supply and Utilization by Station
3-26 2020 and 2030 Station Boardings, Vehicle Trips, and Person Trips Forecasts
3-27 2020 and 2030 Interim Terminus Station Boardings, Vehicle Trips, and Person Trips Forecasts
3-28 Parking Impacts by Alternative
3-29 Existing and Proposed Park-and-Ride Parking Stalls and Forecasted Auto Use

3-30 Average Truck Trips for Construction of Alternatives
3-31 Roadway Construction Impacts by Segment
3-32 PM Peak-Period (3-Hour) Pedestrian and Bicycle Trips Generated at Stations
3-33 2030 2-Hour Peak-Period I-90 Bridge Truck Volumes and Travel Times

4.1-1 Potential Permanent Easements for Public Lands or Facilities
4.1-2 Summary of Property Acquisition Impacts by Segment
4.1-3 Property Acquisitions and Displacements
4.1-4 Commercial Property Availability for Relocation on the Eastside
4.2-1 Generalized Land Uses Within 0.5Mile of Stations
4.2-2 Potential Land Use Conversion to Transportation-Related Land Use
4.2-3 Potential for Station Areas To Support Transit-Oriented Development
4.3-1 Population, Household, and Employment Forecasts by Segment
4.3-2 Revenue Sources: Percent of Total Revenues by City
4.3-3 Property Acquisition Impacts on Businesses and Employees
4.3-4 Comparison of Annual Average Employment Growth and Total Employees Displaced by Segment
4.3-5 Initial Property Tax Impacts on Cities by Alternative
4.3-6 Current and Forecast 2-Hour Peak-Period Freight Truck Volumes and Travel Times across the I-90 Bridge
4.3-7 Direct Expenditures and Direct Employment in Three-County Region from East Link Construction of Preferred Alternative
4.4-1 Demographics within 0.5 Mile of the Project Alternative Stations
4.4-2 Factors Considered in Assessing Impacts on Neighborhoods Within Segment B
4.4-3 Factors Considered in Assessing Impacts on Neighborhoods Within Segment C
4.4-4 Factors Considered In Assessing Impacts on Neighborhoods Within Segment D
4.4-5 Factors Considered In Assessing Impacts on Neighborhoods within Segment E
4.5-1 Visual Characteristics of Project Components
4.5-2 Summary of Changes to Visual Quality by Alternative
4.6-1 Ambient Air Quality Standards by Government Jurisdiction
4.6-2 Ambient Air Quality Monitoring Data at Beacon Hill in Seattle
4.6-3 Regional and Subarea Bus Fleet Mix
4.6-4 CO_2e Emission Rates by Fuel Type
4.6-5 Greenhouse Gas Emissions in Terms of CO_2e During Light Rail Operation
4.6-6 Projected Construction Emissions
4.6-7 CO_2e Emission for Construction of Full-Length Project
4.6-8 Ambient Air Quality Monitoring Data from CO Monitoring Sites in the Project Vicinity
4.6-9 1-hour CO concentrations at Station Platforms
4.7-1 FHWA Traffic Noise Abatement Criteria
4.7-2 Groundborne Vibration and Noise Impact Criteria for Light Rail Transit Service Frequency
4.7-3 Washington State Noise Limits
4.7-4 Washington State Short-Term Noise Exceedance Exemptions
4.7-5 Existing Conditions Noise Monitoring Summary
4.7-6 Summary of Potential Noise Impacts
4.7-7 Summary of Curves with Potential Wheel Squeal
4.7-8 Summary of Potential Vibration Impacts
4.7-9 Maximum Noise Levels for Typical Construction Phases at 50 Feet from the Work Site

4.7-10 Typical Distances from Sources to Vibration and Groundborne Noise Impact
4.8-1 Summary of Wetlands Located in the Study Area
4.8-2 Water Bodies, Aquatic Habitat Quality, and Aquatic Species in the Study Area
4.8-3 Federal and State Species of Concern, Including Threatened and Endangered, Found in Western Washington; Locally Important Wildlife; and Potential Occurrence in East Link Study Area
4.8-4 Anadromous Salmonids in Lake Washington
4.8-5 Potential Permanent Operational Direct Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Habitat
4.8-6 In-Water Construction Work Windows for Listed Species
4.8-7 Potential Temporary Construction Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Resources
4.9-1 303(d) Designated Use Violations (2008)
4.9-2 Existing and Proposed Impervious Areas by Project Build Alternative
4.9-3 Segment D Stream Crossings by Alternative
4.10-1 Utility Data
4.10-2 Existing Daily Vehicle Miles Traveled and Energy Consumption (2005)
4.10-3 Daily Vehicle Miles Traveled and Energy Consumed
4.10-4 Projected Energy Consumption for *Preferred Alternatives*
4.11-1 Potential Geologic Hazards within or Adjacent to Each Segment
4.11-2 Geological Conditions for Tunnel Alternatives
4.11-3 Estimated Waste Volumes and Truck Trips
4.12-1 Number of Hazardous Material Sites within 660 Feet of Each Segment and Alternative
4.12-2 Potential Impacts of High-Risk Hazardous Material Sites within Segment B
4.12-3 Potential Impacts of High-Risk Hazardous Material Sites within Segment C
4.12-4 Potential Impacts of High-Risk Hazardous Material Sites within Segment D
4.12-5 Potential Impacts of High-Risk Hazardous Material Sites within Segment E
4.12-6 Number of Hazardous Material Sites at Maintenance Facilities by Connection from Alternatives
4.13-1 Estimated External Magnetic Fields Near Children's Hospital Bellevue Clinic and Surgery Center Magnetic Resonance Imaging (MRI) Unit
4.13-2 Estimated External Magnetic Fields Near Overlake Portable Center Magnetic Resonance Imaging (MRI) Unit
4.14-1 Fire Department Average Response Times
4.14-2 2008 Violent and Property Crime Rates
4.15-1 Utility Providers in Study Area
4.15-2 Utility Conflict Summary Approximate Length of Relocations and Number of Crossings
4.16-1 List of Historic Properties in Area of Potential Effect
4.17-1 Segment A Parks and Open Spaces Impacts
4.17-2 Segment B Parks and Open Spaces Permanent Impacts
4.17-3 Segment C Parks and Open Spaces Permanent Impacts
4.17-4 Segment E Parks and Open Spaces Permanent Impacts
4.17-5 Segment B Required Parks Construction Area
4.17-6 Segment C Required Parks Construction Area
4.17-7 Segment E Required Parks Construction Area
4.17-8 Potential Mitigation for Identified Impacts

6-1 Summary of East Link Alternatives
6-2 Average 2030 Door-to-Door Peak-Period Transit Travel Time Savings with East Link Compared to No Build Alternative
6-3 Project-Wide Range of Impacts by Impact Category
6-4 Summary of Differentiating Environmental Impacts for East Link Build Alternatives
6-5 Level of Construction Risk by Alternative
6-6 Estimated Cost by Alternative

7-1 East Link Draft EIS – Responses to Common Comments
7-2 Summary Comparison of B7R and B7/C9T

Exhibits

1-1 East Link Project Vicinity Map
1-2 Location of High-Growth Employment and Population Centers in East Link Corridor
1-3 Failing Intersections in South and Downtown Bellevue in 2030
1-4 Failing Intersections in Bel-Red, Overlake, and Downtown Redmond in 2030
1-5 History of High-Capacity Transit in the East Corridor
1-6 I–90 Two-Way Transit and HOV Operations Project

2-1 East Link Project Segments and Alternatives
2-2 East Link Preferred Alternative
2-3 Stages for Implementation of I-90 Two-way Transit and HOV Operations Project Alternative
2-4 I-90 Existing Conditions and No Build Alternative with I-90 Two-Way Transit and HOV Operations Project Stages 1 and 2 only
2-5 I-90 No Build Alternative with I-90 Two-Way Transit and HOV Operations Project Stages 1-3
2-6 Typical Light Rail Car
2-7 At-Grade Center-Running
2-8 Retained Cut
2-9 Retained Fill, Center-Running
2-10 Retained Fill, Side-Running
2-11 Elevated Center-Running
2-12 Elevated Side-Running
2-13 Cut-and-Cover Tunnel
2-14 Bored Tunnel
2-15 Typical Station Designs
2-16 Segment A, Interstate 90, Alternative A1
2-17 Segment B, South Bellevue Alternatives
2-18 Segment C, Downtown Bellevue Alternatives
2-19 Segment D, Bel-Red/Overlake Alternatives
2-20 Segment E, Downtown Redmond Alternatives
2-21 I-90 with *Preferred Alternative A1*
2-22 *Preferred 112th SE Modified Alternative (B2M) to C11A*
2-23 *Preferred 112th SE Modified Alternative (B2M) to C9T*
2-24 Bellevue Way Alternative (B1)
2-25 112th SE At-Grade Alternative (B2A)
2-26 112th SE Elevated Alternative (B2E)

2-27 112th SE Bypass Alternative (B3)
2-28 BNSF Alternative (B7)
2-29 At-Grade Track with Planned Trail in Former BNSF Railway Corridor (looking north)
2-30 *Preferred 108th NE At-Grade Alternative (C11A)*
2-31 *Preferred 110th NE Tunnel Alternative (C9T)*
2-32 Bellevue Way Tunnel Alternative (C1T)
2-33 106th NE Tunnel Alternative (C2T)
2-34 108th NE Tunnel Alternative (C3T)
2-35 Couplet Alternative (C4A)
2-36 C4A, At-Grade, Side Running on 110th and 108th Avenue NE
2-37 112th NE Elevated Alternative (C7E)
2-38 110th NE Elevated Alternative (C8E)
2-39 110th NE At-Grade Alternative (C9A)
2-40 114th NE Elevated Alternative (C14E)
2-41 City of Bellevue Proposed B7/C9T Revised (B7R)
2-42 *Preferred Alternative D2A*
2-43 NE 16th Elevated Alternative (D2E)
2-44 NE 20th Alternative (D3)
2-45 SR 520 Alternative (D5)
2-46 *Preferred Marymoor Alternative (E2)*
2-47 Redmond Way Alternative (E1)
2-48 Leary Way Alternative (E4)
2-49 Prototypical Layout of East Link Maintenance Facility
2-50 Overhead Catenary System
2-51 Traction Power Substation
2-52 Crossover Tracks
2-53 *Preferred Alternative C11A* Construction Staging Areas
2-54 *Preferred Alternative C9T* Construction Staging Areas
2-55 Alternative C1T Construction Staging Areas
2-56 Alternative C2T Construction Staging Areas
2-57 Alternative C3T Construction Staging Areas
2-58 Alternative C4A Construction Staging Areas
2-59 Alternative C7E Construction Staging Areas
2-60 Alternative C8A Construction Staging Areas
2-61 Alternative C9A Construction Staging Areas
2-62 Alternative C14E Construction Staging Areas
2-63 Overall Project Cost Range
2-64 Segment A Cost Estimate
2-65 Segment B Cost Estimate
2-66 Segment C Cost Estimate
2-67 Segment D Cost Estimate
2-68 Segment E Cost Estimate
2-69 Maintenance Facilities Cost Estimate

3-1 Transportation Analysis Study Area, Segment A
3-2 Transportation Analysis Study Area, Segments B and C
3-3 Transportation Analysis Study Area, Segments D and E
3-4 Existing PM Peak-Hour Screenline Mode Share
3-5 PSRC 2030 PM Roadway Volume-to-Capacity Ratios without East Link
3-6 2030 PM Peak-Hour Mode Share at Screenlines
3-7 2020 and 2030 PM Peak-Period Service Frequency LOS
3-8 2020 and 2030 Hours of Service LOS
3-9 East Link Travel Times Between Key Stations
3-10 2030 Projectwide Daily Ridership
3-11 I-90 Existing AM and PM Peak-Hour Person Throughput by Mode at Screenlines 2 and 3
3-12 I-90 Existing Year AM and PM Peak-Period Vehicle Speeds in General Purpose Lanes
3-13 I-90 Two Way Transit and HOV Project Stages
3-14 I-90 Configuration Before and After East Link
3-15 Screenline 2 (I-90 Only) 2030 Mode Share
3-16 I-90 2030 AM and PM Peak-Hour Person Throughput across Lake Washington
3-17 2020 and 2030 I-90 Peak-Hour Person Throughput by Mode at Lake Washington (Screenline 2)
3-18 2020 and 2030 I-90 Peak-Hour Person Throughput by Mode at Mercer Slough (Screenline 3)
3-19 I-90 Year 2030 AM and PM Peak-Period Vehicle Speeds in General-Purpose Lanes
3-20 2030 AM No Build and Build Level of Service at Intersections, Segment A
3-21 2030 PM No Build and Build Level of Service at Intersections, Segment A
3-22 2030 PM No Build and Build Level of Service at Intersections, Segment B
3-23 2030 PM No Build and Build Level of Service at Intersections, Tunneled Alignments, Segment C
3-24 2030 PM NO Build and Build Level of Service at Intersections, Non-Tunneled Alignments, Segment C
3-25 2030 PM No Build and Build Level of Service at Intersections, Segment D
3-26 2030 PM No Build and Build Level of Service at Intersections, Segment E
3-27 Pedestrian Walking Areas by Stations in Downtown Bellevue and Bel-Red Area, Segments C and D
3-28 I-90 Existing 24-Hour Truck Volumes

4.2-1 City of Seattle Generalized Zoning, Segment A – Seattle
4.2-2 City of Mercer Island Generalized Zoning, Segment A – Mercer Island
4.2-3 City of Bellevue Generalized Zoning, Segment B
4.2-4 City of Bellevue Generalized Zoning, Segment C
4.2-5 City of Bellevue and Redmond Generalized Zoning, Segment D
4.2-6 City of Redmond Generalized Zoning, Segment E
4.3-1 Unemployment Rates, 1997 to 2009
4.4-1 Neighborhoods and Public Services, Segment A – Seattle
4.4-2 Neighborhoods and Public Services, Segment A – Mercer Island
4.4-3 Neighborhoods and Public Services, Segment B
4.4-4 Neighborhoods and Public Services, Segment C
4.4-5 Neighborhoods and Public Services, Segment D
4.4-6 Neighborhoods and Public Services, Segment E
4.5-1 Visual Quality, Segment A
4.5-2 Visual Quality, Segment B
4.5-3 Visual Quality, Segment C

4.5-4 Visual Quality, Segment D
4.5-5 Visual Quality, Segment E
4.6-1 Comparison of National and Washington Greenhouse Gas Emissions
4.6-2 Segment A Intersections Analyzed for CO Concentrations with WASIST Model
4.6-3 Segment B and C Intersections Analyzed for CO Concentrations with WASIST Model
4.6-4 Segment D and E Intersections Analyzed for CO Concentrations with WASIST Model
4.7-1 Typical 24-hour Ldn Noise Levels and Land Use Compatibility
4.7-2 Examples of Groundborne Vibration Levels and Human/Structural Response
4.7-3 FTA Project Noise Impact Criteria
4.7-4 Noise and Vibration Monitoring Locations, Segments A, B, and C
4.7-5 Noise and Vibration Monitoring Locations, Segments D and E
4.7-6 Noise Level Reduction with Distance (train bells and warning gate bells)
4.7-7 Noise and Vibration Impacts, Segment A *Preferred Alternative A1*
4.7-8 Noise and Vibration Impacts, Segments B and C Preferred Alternative
4.7-9 Noise and Vibration Impacts, Segments D and E Preferred Alternative
4.7-10 Noise and Vibration Impacts, Segments B and C Other Alternatives
4.7-11 Noise and Vibration Impacts, Segments D and E Other Alternatives
4.8-1 Vegetation/High-Value Wildlife Habitat, Aquatic Habitat, and Wetlands, Segment B
4.8-2 Vegetation/High-Value Wildlife Habitat, Aquatic Habitat, and Wetlands, Segment C
4.8-3 Vegetation/High-Value Wildlife Habitat, Aquatic Habitat, and Wetlands, Segment D
4.8-4 Vegetation/High-Value Wildlife Habitat, Aquatic Habitat, and Wetlands, Segment E
4.8-5 Mercer Slough Buffer along 112th Avenue SE
4.8-6 Sturtevant Creek upstream of NE 8th Street
4.8-7 Sturtevant Creek next to Hilton Hotel at 114th Avenue SE
4.8-8 West Tributary to Kelsey Creek at Detention Pond
4.9-1 Water Resources Overview, Segments A, B, C, D, and E
4.9-2 Water Resources, Segment B
4.9-3 Water Resources, Segment C
4.9-4 Water Resources, Segment D
4.9-5 Water Resources, Segment E
4.10-1 Average Fuel Consumption Rates for Automobiles
4.11-1 Project Location and Topography
4.12-1 High Risk Hazardous Material Sites Within 1/8 Mile of Alternatives, Segments B and C
4.12-2 High Risk Hazardous Material Sites Within 1/8 Mile of Alternatives, Segments D and E
4.15-1 Utility Conflicts, Segment B
4.15-2 Utility Conflicts, Segment C
4.15-3 Utility Conflicts, Segment D
4.15-4 Utility Conflicts, Segment E
4.16-1 Cultural Resources, Segments A, B, C, D, and E
4.16-2 United States Immigration Station and Assay Office Building
4.16-3 Publix Hotel
4.16-4 Jose Rizal 12th Avenue South Bridge
4.16-5 Mount Baker Ridge Tunnel
4.16-6 I-90 Lake Washington Highway Segment

4.16-7 Will H. Thompson House
4.16-8 Endresen Residence
4.16-9 Romaine Electric/Washington Iron Works Pattern Shop
4.16-10 The Winters House
4.16-11 Pilgrim Lutheran Church
4.16-12 Contributing Properties to the Potential Surrey Downs Historic District
4.16-13 Mithun & Neslund Design on 109th Avenue SE in Surrey Downs Subdivision
4.16-14 Safeway Store
4.16-15 Former Bellevue Fire Station, 14822 NE Bellevue-Redmond Road

Chapter 1

Purpose and Need for East Link Project

1.1 Purpose of the Project

The purpose of the East Link Project is to expand the Sound Transit Link light rail system from Seattle to Mercer Island, Bellevue and Redmond via Interstate 90 (I-90) and to provide a reliable and efficient alternative for moving people throughout the region.

1.1.1 Project Vicinity

The project corridor is located in King County, Washington, the most densely populated county of the Puget Sound region. The project vicinity includes urban centers on both sides of Lake Washington (Exhibit 1-1). The project corridor originates at the Downtown Seattle Transit Tunnel at the International District/Chinatown Station, and then travels eastward on I-90 to the Rainier Valley Neighborhood before entering the Mount Baker Tunnel and crossing Lake Washington on the I-90 Floating Bridge to the Mercer Island Town Center. It remains on I-90, crossing the East Channel Bridge to the City of Bellevue. The project corridor extends north from I-90 between Bellevue Way and the I-405/former BNSF Railway corridor toward Downtown Bellevue. From Downtown Bellevue, the project corridor extends east, parallel to State Route (SR) 520 through Bellevue's Bel-Red subarea and Overlake, a subarea in the City of Redmond. From Overlake, the project corridor continues northeast parallel to SR 520 to Downtown Redmond, which is the terminus of the project.

1.1.2 Support for Project Purpose

The purpose of the East Link Project is based upon over 40 years of continuous and cooperative regional and local transportation planning. The research, joint planning efforts, and decision-making processes are recorded in *East Corridor High-Capacity Transit Mode Analysis History* (Sound Transit, 2006) and summarized in Section 1.3 of this chapter. The conclusions and findings from that history were used to develop the following support for the East Link Project purpose:

- Improve speed and reliability and expand the region's transportation system capacity through an exclusive light rail transit right-of-way, while preserving the environment.
- Increase mobility and accessibility to and from the region's highest employment and housing concentrations.

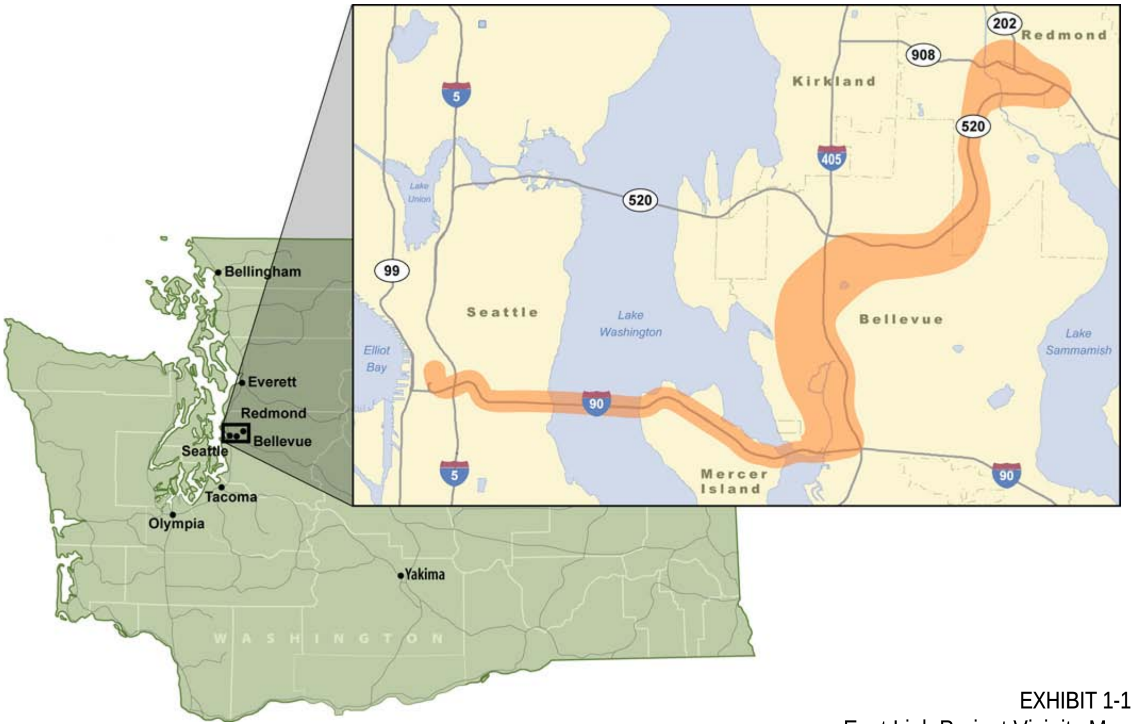

EXHIBIT 1-1
East Link Project Vicinity Map

- Support regional land use and transportation plans—*VISION 2040* (Puget Sound Regional Council [PSRC], 2009) and *Transportation 2040* (PSRC, 2010)—to direct growth into high-density urban and manufacturing centers in Downtown Bellevue, Overlake, and Redmond by providing a high-capacity transit (HCT) connection between these centers, Seattle, and other regional destinations.
- Implement the goals and objectives identified in Sound Transit's Long-Range Plan (Sound Transit, 2005), which guides the development of the regional HCT system. The main transportation goal is to "provide a public transportation system that helps ensure long-term mobility, connectivity, and convenience for the citizens of the Puget Sound Region for generations to come" and to "provide reliable, convenient, and safe public transportation services between regional growth centers and create an integrated system of transit services."
- Implement the HCT element of the Washington State Department of Transportation (WSDOT*) I-90 Two-Way Transit and High Occupancy Vehicle (HOV) Operations Project Final Environmental Impact Statement* (EIS) (WSDOT and Sound Transit, 2004); the Federal Highway Administration (FHWA) Record of Decision (FHWA, 2004); the Federal Transit Administration (FTA) Record of Decision (April 15, 2011); and the August 2004 Amendment to the 1976 Memorandum Agreement between King County, City of Bellevue, City of Seattle, City of Mercer Island, Washington State Transportation Commission, and Sound Transit (City of Mercer Island et al., 2004). These documents stipulate that the ultimate configuration of I-90 should accommodate all phases of the I-90 Two-Way Transit and HOV Operations Project with HCT in the center lanes. The amendment directs the agencies "to provide high-capacity transit in the center lanes of I-90 between Bellevue and Seattle as quickly as possible..." The amendment and Final EIS define HCT as "… a transit system operating in dedicated right-of-way, such as light rail, monorail, or a substantially equivalent system."
- More fully develop a regional transit system that would integrate with the Central Link light rail line, providing direct connections among the largest urban centers in King County.
- Fulfill Sound Transit's legislative mandate to meet public transportation and mobility needs for HCT infrastructure in the Central Puget Sound region, as established by the State High-Capacity Transportation Systems Act (Ch. 81.104 Revised Code of Washington).

1.2 Need for East Link Project

Current and projected population and employment trends reveal a need to provide light rail transit between Seattle and the Bellevue and Redmond urban centers. This section explains why existing transit will not be able to serve the future transit needs in the project corridor. In brief, these reasons are as follows:

- **Increased demand for transit services** across Lake Washington is expected to double by 2030 as a result of residential and employment growth on both sides of Lake Washington.
- **Regional urban center growth plans supported by HCT investments** in accordance with PSRC's adopted *Transportation 2040*.
- **Increased congestion on I-90** will further limit transit performance as the I-90 corridor reaches maximum vehicle capacity during peak-hour travel as early as 2015 (WSDOT, 2006).
- **Operating deficiencies in regional bus transit service** will continue to occur due to lower speeds and decreasing reliability.
- **Limited transit capacity and connectivity** between the areas of highest employment density in the region will occur due to constraints of the current road system.

1.2.1 Growth and Increased Demand for Transit Services

Regional planning for growth and transportation is conducted by PSRC, the metropolitan planning organization for the Puget Sound region, which includes King, Kitsap, Pierce, and Snohomish Counties. Population and employment growth in this region is strong. Rapid population and employment growth in the Puget Sound region in recent decades has exceeded national averages (PSRC, 2006). Between 2000 and 2030, PSRC projections show that the region's population will increase almost 40 percent (an additional 1.3 million people). Corridor-specific population projections are shown in Table 1-1.

Regional employment will grow approximately 42 percent (more than 737,000 new jobs); Table 1-2 lists city-specific employment projections. More than 30 percent of the region's employment is in the Downtown Seattle, Bellevue, and Redmond growth centers, and regional planning has focused new housing and employment growth within these urban areas.

TABLE 1-1

[c] Forecast Analysis Zones (FAZs) 4505, 4506, 4810, 4820, 4900, 5010, and 5020 (PSRC, 2006) and 5205 (PSRC, 2009).

[d] FAZs 5415 and 5425 (PSRC, 2009) and 5426 (PSRC, 2006).

Exhibit 1-2 shows the location of high-growth population and employment centers in 2030 that would be served directly by the East Link Project.

This projected growth, however, will increase the daily hours of delay 83 percent on regional freeways (I-90, I-405, and I-5) and 66 percent on arterials between 2006 and 2040, according to the *Transportation 2040* Final EIS. Implementing PSRC's *Transportation 2040* plan, which includes the East Link Project, would reduce delays on freeways by 32 percent and increase delay on arterials by 55 percent from 2006 to 2040.

In response to the combination of population and employment growth and associated congestion, transit demand across Lake Washington is expected to double over the next 20 years. The vehicle demand for I-90 is expected to grow by at least 50 percent.

As growing populations increase, residents and employees require more transportation options such as dedicated transit because single-occupant vehicle travel times are expected to increase and parking options decrease. Increasing the proportion of travel by transit, HOVs, and walking or bicycling reduces dependence on single-occupant vehicles and alleviates pressure on limited road capacity.

Finally, surges in gasoline prices over the 2007- 2008 period and more recently have influenced people's daily transportation choices. American Public Transportation Association (APTA) recorded strong increases in transit ridership within United States' metropolitan cities (APTA, 2008). In the Puget Sound Region, the 2008 winter quarter showed a 15 percent increase in transit ridership as compared to the previous winter quarter. This trend is likely to continue, which increases the pressure for expanding transit options.

1.2.2 Regional Urban Center Growth Plan Supported by HCT Investments

PSRC's *VISION 2040*, the regional land use plan, focuses growth in urbanized areas. *VISION 2040* re-dedicates the region's commitment, as stated in *VISION 2020*, to enable residents to live near jobs and other urban activities; to help strengthen existing communities; and to promote bicycling, walking, and transit use. These focus areas are identified as "urban centers."

In response to the state Growth Management Act (GMA), PSRC's metropolitan transportation plan, *Transportation 2040*, establishes policies that prioritize new transportation services in areas that accept an increased share of growth. Because of limited funding, the Regional Transportation Improvement Program strategically focuses funding on development of regional growth centers and the corridors between these centers. The goal of this prioritization is to concentrate growth in existing urbanized areas, which is considered the most efficient way to serve a greater share of the region's population.

This regional growth strategy involves strengthening and revitalizing existing centers that offer a wide variety of jobs, services, and important civic and cultural resources as well as encouraging development in suburban areas that are emerging as new community and regional hubs. *VISION 2040* and *Transportation 2040* recognize areas of Seattle, Bellevue, and Redmond as regional growth centers. Specifically, the growth centers of Downtown Seattle, Downtown Bellevue, Overlake, and Redmond are in the proposed East Link Project's study area. In addition, the study

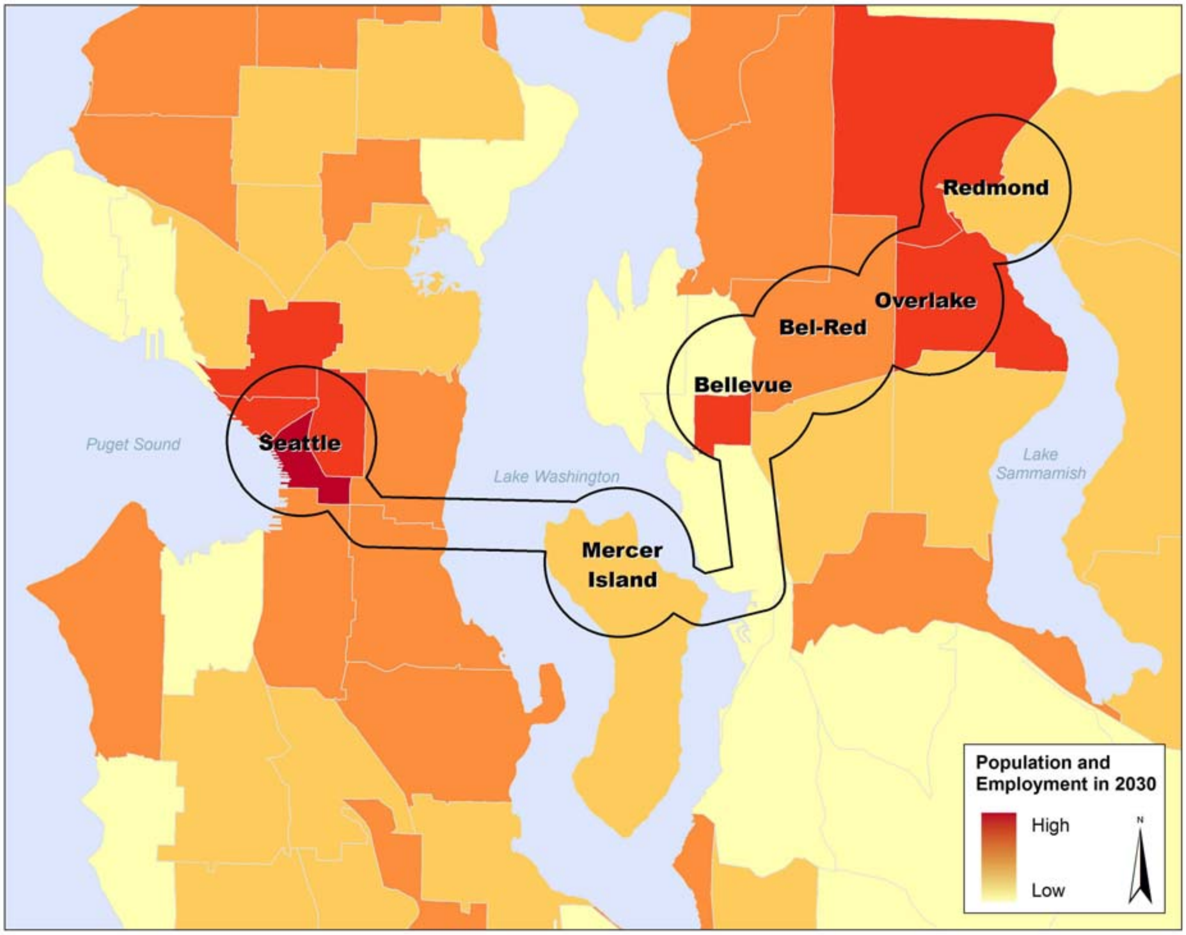

EXHIBIT 1-2
Location of High-Growth Employment and Population Centers in East Link Corridor

area includes connections to identified urban centers that are going to be served by the completion of Central Link, such as Capitol Hill, the University District, and the airport.

Today, Redmond and Bellevue are rapidly developing and expanding, causing them to approach density goals (targets) earlier than expected and increasing the pressure to implement efficient transportation alternatives to improve connections between these regional urban centers (Table 1-3). By 2000, the Downtown Bellevue regional growth center had reached 60 percent of its population target, 64 percent of its housing target, and 75 percent of its employment target for 2030. The (Downtown) Redmond regional growth center had reached 32 percent of its population target, 41 percent of its housing target, and 56 percent of its employment target for 2030. With ongoing development, Bellevue and Redmond are on track to meet their targets by 2030 or earlier.

Seattle, Mercer Island, Bellevue, and Redmond have adopted or are adopting plans to create concentrated centers of high-density, mixed-use, pedestrian-scale development, based upon the assumption that they would receive HCT to support changing transportation needs. Methods to increase density and promote nonmotorized transportation in these plans include increasing maximum building height; requiring sidewalks; limiting parking availability; and integrating multiple land uses such as residential, commercial, office, and public spaces. In Seattle, the *Center City Seattle* (2007c) strategy identifies 10 specific neighborhoods within the city that will represent a new urban identity for Seattle's urban core, while creating jobs and providing economic opportunities. One of those neighborhoods, the International District/Chinatown, would be directly served by the East Link Project, while others such as Capitol Hill, Pike/Pine, First Hill, and the Commercial Core would be served through connections to Central Link.

Mercer Island's comprehensive plan seeks to maintain the city primarily as a community of single-family homes and focuses mixed-use growth in the Town Center adjacent to I-90. Bellevue has adopted the *Downtown Subarea Plan* (2004) and *Bel-Red Subarea Plan* (2008).

TABLE 1-3
Expected Growth in Seattle, Bellevue, and Redmond Urban Centers

N/A not available

These plans establish how Bellevue will accommodate planned increases in housing and jobs while trying to reduce the anticipated traffic congestion that could occur if unchecked growth were to occur. The *Bel-Red Subarea Plan* was developed to accommodate HCT in this corridor. Finally, Redmond has adopted the *Overlake Neighborhood Plan* (2007) and *Downtown Neighborhood Plan* (2005). Overlake (a neighborhood of Redmond) was previously identified as one of eight manufacturing/ industrial centers due to the presence of Microsoft headquarters, among other high-tech industries. In 2007, its designation was changed to an urban center, reflecting an expected increase in residential, commercial, and office uses in the area. Additionally, in anticipation of HCT, the *Overlake Neighborhood Plan* was revised to allow building heights to increase from five to nine stories in some areas, to develop 152nd Avenue NE as a pedestrian-friendly corridor, and to create pathways to provide connections for nonmotorized transportation uses.

Table 1-4 provides estimates of planned development in the major growth centers identified in the East Link Project corridor as of 2008. The data provided for Downtown Bellevue are for projects under construction or under review, while data provided for the other centers are for projects proposed in recent planning efforts.

1.2.3 Increased Congestion on I-90

There are only two crossings of Lake Washington between Seattle and the Eastside: SR 520 and I-90. Planning to replace the SR 520 bridge and improve transportation in that corridor is still underway. In the I-90 corridor, Sound Transit and WSDOT have been implementing the initial phases of the I-90 Two-Way Transit and HOV Operations Project, which will ultimately add HOV lanes to the outer roadways. However, even with planned improvements on the SR 520 and I-90 bridge crossings, the travel times on I-90 are expected to increase.

Recent WSDOT and Sound Transit transportation models predict that I-90 across Lake Washington will reach its vehicle capacity during the peak periods as early as 2015 (WSDOT, 2006). Reaching capacity in such a short time frame will limit roadway performance and its ability to accommodate the increase in traffic volume associated with the expected job and housing growth in Seattle and Eastside communities. As a major freight corridor, increased traffic demand also adversely affects freight mobility.

TABLE 1-4
Planned New Development

	New Housing Units	New Retail (square feet)	New Office Space (square feet)

Even with the roadway improvements already constructed or planned for I-90, the interchanges at I-405 and Bellevue Way on the Eastside and at I-5 in Seattle constrain I-90's vehicle capacity. Further improvements are physically constrained by existing urban development and infrastructure.

In the morning (AM) and afternoon (PM) peak hours, the travel times that exist now are expected to get worse. By 2030, Sound Transit and WSDOT project that the PM peak hour travel time between I-405 and Seattle will increase by about 60 percent westbound (reaching 30 minutes) and by approximately 20 percent eastbound (reaching 20 minutes). In the AM peak hour, travel times are expected to increase even more substantially. In both the westbound and eastbound directions, the travel time will increase by approximately 70 percent. These increases reflect the fact that there are high-density urban centers on both sides of the lake, resulting in a more balanced commute pattern in either direction, rather than the historical pattern of commuters going to work in Seattle and living in East King County. The largest increase in travel times is forecast in the reverse-peak direction, which means that travel in both directions will become more balanced.

As with increases in travel time, the peak period of congestion on I-90 will increase by at least 1 hour in each direction. By year 2030, the duration of congestion in the westbound general-purpose lanes during the afternoon is expected to increase from 1.5 hours to 2.5 hours or longer. In the eastbound direction during the PM peak, the duration of congestion in the general-purpose lanes will increase from just over 1 hour to more than 2 hours. Congestion extending outside the peak commuting hours will negatively affect the transportation system's reliability and its ability to serve demand, and it will further constrain the region's mobility and movement of goods.

Even though the morning westbound and afternoon eastbound HOVs and transit on I-90 can use the reversible center roadway, which is two lanes, the capacity constraints on either end only allow it to carry the equivalent of about one lane of traffic. The center reversible roadway will continue to be underutilized in the future because of constraints in accessing these lanes, which prevents the center roadway from realizing its full capacity. However, the outer roadway is expected to reach its maximum vehicle capacity by 2015. Increased congestion will further exacerbate bus service delays.

1.2.4 Operating Deficiencies in Regional Bus Transit Service

As congestion throughout the region increases, it is imperative to examine options and take action to overcome the limitations in the existing regional bus system that are caused by the lower speeds, decreasing reliability, and service capacity constraints of buses.

Reliability is defined as the degree to which transit service can be counted on for consistent, on-time performance. Current transit service in the project vicinity has poor reliability due to congestion on local arterials and I-90 (King County, 2007), and the average transit route at the International District/Chinatown Station, Mercer Island, and Bellevue Transit Center has the lowest reliability rating—level of service (LOS) F (Transportation Research Board, 2003). This reliability rating means that routes are late at least 50 percent of the time. Most transit routes at Overlake Transit Center and Redmond Transit Center also operate with LOS F.

The urban center-to-urban center express routes are Sound Transit's Seattle to Bellevue 550 and the Seattle to Redmond 545. These express service routes feed a broader network of King County Metro buses. When the 550 and 545 are late, passenger connections are in jeopardy. Westbound Express Route 550 trips from Bellevue to the Mercer Island Transit Center are late during the peak period 50 percent of the time and when it reaches Seattle, it is late 70 percent of the time during the peak period. To avoid being late no more than twice a month, riders on this route need to build an additional 15 minutes into their daily schedule. This lack of reliability makes it difficult for users to have confidence that they will reach their destinations on time and it reduces the attractiveness of transit service throughout the project corridor.

Bus speeds from Seattle to Bellevue and from Bellevue to Redmond are projected to decrease by 30 percent or more by 2030, even assuming major I-90 infrastructure improvements (Sound Transit, 2006). Transit patronage is highly sensitive to travel time expectancy. Increasing use of HOV lanes and added congestion on the local and arterial streets in the corridor threatens to further worsen the urban center-to-urban center bus travel times. Because speeds on HOV lanes without a separating barrier are affected by congestion in adjacent lanes, transit travel time will likely mirror congestion periods, thus reducing the benefits of transit. At present, bus travel times in the corridor are typically over 30 minutes between the International District/Chinatown Station and the Bellevue Transit

Center in the PM peak, with an average bus speed of 16 miles per hour. By 2030, speeds on the same bus route are expected to decrease to 11 miles per hour based on Sound Transit model projections, with the bus travel time between the International District/Chinatown Station and the Bellevue Transit Center in the PM peak reaching close to an hour long (Sound Transit, 2006). If unhindered, bus travel time for this trip is expected to be less than 25 minutes.

Transit reliability and speed of travel are also currently negatively affected by congestion on arterial routes, such as Bellevue Way SE, NE 8th Street, 148th Avenue NE, and 156th Avenue NE. Within Bellevue and Redmond, several major bus routes operate on these and other arterial roads. Congestion on many of these streets is also anticipated to worsen over the next 20 years. Exhibits 1-3 and 1-4 illustrate key intersections in the project vicinity that are expected to be at or below failing conditions (LOS E or F) by 2030. These intersections affect travel on the surrounding roadways, including transit service.

The Bellevue Way and 112th Avenue SE corridors between Downtown Bellevue and I-90 are substantially congested during the PM peak period, and the congestion is expected to get worse. In particular, the intersection of Bellevue Way SE and the South Bellevue Park-and-Ride Lot operates at LOS F, with southbound vehicle queues often extending beyond the 112th Avenue SE intersection. Sound Transit Route 550 is often caught in this afternoon congestion, which contributes considerably to the poor speed and reliability of this route. Congestion near the Wilburton Park-and-Ride Lot along SE 8th Street is also high during the PM peak period because it is near the I-405 ramps.

Within Downtown Bellevue, 10 intersections are expected to operate at LOS E or F by 2030. Many transit routes in the east corridor travel through these intersections to access the Bellevue Transit Center. Five intersections along 112th Avenue SE and four intersections along NE 8th Street are expected to operate poorly (either at LOS E or F). Congestion on these key arterials affects many of the transit routes in Downtown Bellevue, and it restricts the ability for these transit routes to maintain their schedules, affecting reliability.

The Bel-Red corridor from Downtown Bellevue to Overlake includes several intersections that operate at a LOS D or worse, and by 2030, most of the intersections in the Overlake area east of 140th Avenue NE will operate at LOS E or F, causing substantial delays to buses traveling along NE 24th Street, Bel-Red

Road, 148th Avenue NE, 156th Avenue NE, and NE 20th Street. These arterials serve two transit facilities in the project vicinity: Overlake Village and Overlake Transit Center. The congestion on these arterials is a result of major employment and retail centers located in this area, as well as congestion on SR 520, which forces through traffic onto these arterials. Congestion on these arterials will affect transit speeds and negatively affect reliability of routes throughout the region. Transit access to and from SR 520 is also hindered by the high traffic volumes using the interchanges at 148th Avenue NE, NE 40th Street, and NE 51st Street. Transit performance is at LOS F conditions approaching Downtown Redmond and at Redmond's two transit centers due to transportation congestion at the SR 520 access ramps and from West Lake Sammamish Parkway and Redmond Way (SR 202). These conditions affect bus speed and reliability.

As development plans in the project vicinity encourage development of denser and more mixed uses, access and traffic constraints into and out of the urban centers will continue to hinder the ability of regional buses to meet the larger transit network needs and therefore reduce transit's ability to provide a viable alternative to the automobile. If a more reliable system is made available, overall dependence on one mode of transportation will decrease and travel via all modes will improve, allowing the region's urban centers to efficiently absorb growth.

1.2.5 Limited Transit Capacity and Connectivity

Infrastructure constraints limit the ability of transit to meet the untapped demand for reliable daily business and commuter travel, as explained in Sections 1.2.3 and 1.2.4. Even with increases in congestion and delays, the preferred mode of travel across I-90 is not expected to substantially change from today's preference for single-occupant vehicles to bus transit service. Because of poor connectivity and speed of travel between destinations, more than 60 percent of people using I-90 to cross Lake Washington in 2030 are projected to use single-occupant vehicles in the AM peak period and more than 50 percent in the PM peak period. Existing bus routes connecting urban centers have to use the same roadways as other vehicles and therefore cannot compete with the door-to-door service of the single-occupant vehicles unless transit can save travelers time. Furthermore, there are physical constraints to widening many of the roadways, such as I-5 and the connections between I-90 and its adjoining arterials, which are at capacity.

Bus transit capacity is also limited within the central business districts within the project vicinity. In the Seattle Downtown Transit Tunnel, bus operations will decrease and eventually be eliminated as light rail ridership on Central Link and the frequency of light rail trains increases. This will redirect buses to already congested urban surface streets in Downtown Seattle, increasing travel time and decreasing reliability for these routes. In Downtown Bellevue, the 14 transit bays at the Bellevue Transit Center currently must accommodate multiple bus routes on tight schedules during peak travel periods. Frequently, buses that are on time here must wait while delayed buses board passengers, thus causing delays for these routes as well. In addition, local arterial capacity and on-street stops will limit the ability to increase the frequency of buses. More frequent bus service may increase capacity for users, but congestion still limits travel time, which ultimately determines the ability for transit to attract passengers.

The urban center-to-urban center connections determine the effectiveness of the overall transit system. Increasing center-to-center transit service reliability would help passengers meet transit connections and make it easier to depend on transit as a viable alternative mode to the automobile. Also, adding dependable service and capacity would improve economic linkages across Lake Washington, offer increased employment-to-housing connections, and expand the functionality of the transit service in the Puget Sound Region.

1.3 Brief History of East Corridor

The East Link Project builds on the conclusions of previous planning, studies, and public involvement processes dating back to the mid-1960s. Sound Transit has assembled the *East Corridor High-Capacity Transit Mode Analysis History* (Sound Transit, 2006) documenting the outcome of this local public transportation planning process, which forms the basis for the Purpose and Need statement for the East Link Project EIS. Consistent with the memorandum titled *Integration of Planning and NEPA Processes* (Appendix A to 49 Code of Federal Regulations [CFR] Part 613), the decision process is based on comprehensive studies that were completed in cooperation with state and local agencies and broad public input. In particular, the Sound Transit Board made the following two major decisions after extensive evaluation and review with other agencies and the public before beginning this East Link Project EIS:

- Regional HCT to the Eastside via I–90 is necessary.

- Light rail is the preferred HCT technology for the I–90/East Corridor connecting Seattle, Mercer Island, Bellevue, Overlake, and Redmond.

The following subsections summarize this history, the involvement of agencies and the public, and the results of the extensive study of HCT.

1.3.1 Evaluation of Regional HCT to the Eastside via I-90

The history of HCT in the East Corridor is illustrated at a glance in Exhibit 1-5. Although local jurisdictions had earlier reviewed HCT options for regional travel, the first official public action was sought in 1968. A bond measure proposing an extensive rail system for King County was put to voters in 1968 and again in 1970. The measures received support but did not pass.

The State of Washington, local jurisdictions, and transit agencies have been involved in studying transit options across Lake Washington. In 1976, after extensive review and discussion, a memorandum agreement for I–90 was signed by the Cities of Seattle, Mercer Island, and Bellevue; King County; Metro Transit; and the State Highway Commission that confirmed the configuration of the I-90 roadway and specified that the I–90 center roadway should be designed and constructed for future conversion to fixed guideway transit (i.e., rail). (City of Seattle et al., 1976).

In 1981, PSRC (formerly the Puget Sound Council of Governments [PSCOG]) conducted a study to evaluate and prioritize major corridors for HCT in the Puget Sound region for 1990 and beyond. The East corridor from the Seattle Central Business District across I–90 to northeast Bellevue was ranked second highest, with only the north corridor from the Seattle Central Business District to Snohomish County ranking higher (PSCOG, 1981). The Regional Transportation Plan Update (PSCOG, 1982) was amended in September 1982 to include this prioritization. It stated that, because of high peak-period volumes projected in the major corridors, an HCT system would be required to serve high volumes of people, and it identified light rail as a feasible alternative.

In the 1990s, in response to an advisory ballot measure passed by King County voters, the region began the planning work associated with developing a regional HCT system. In August 1990, a regional planning entity, the Joint Regional Policy Committee (JRPC), was formed through an interlocal agreement among the transit agencies of Pierce, King, and Snohomish Counties to coordinate regional transit planning (consistent with Chapter 81.104 Revised Code of Washington [RCW]). Four broad regional HCT system plan alternatives were evaluated in an EIS, including a no-build alternative, a transportation systems management (TSM) alternative, an exclusive bus transitway/TSM option, and a rail/TSM option. In 1993, following approximately 4 years of study and extensive public involvement, the JRPC identified rail/TSM as the preferred system alternative and, specifically, rail as the preferred HCT mode on I–90. Next, with approval by the Snohomish, King, and Pierce county councils, the Central Puget Sound Regional Transit Authority (RTA), now known as Sound Transit, was formed later in 1993 (consistent with Chapter 81.112 RCW).

In 1996, the voters approved Sound Transit's (i.e., RTA's) first phase of HCT investments in the regional transit investment plan called "Sound Move" (Sound Transit, 1996a). Sound Move included two-way bus transit and HOV improvements on I–90 between Seattle and Bellevue. The Sound Transit Board adopted Sound Move, along with *The Regional Transit Long-Range Vision* (Sound Transit, 1996b), which identified the framework for HCT investments in the region, including potential for future light rail extensions. The *Long-Range Vision* and *Sound Move* plans reflected public input on regional priorities and were consistent with Sound Transit's enabling legislation (which explicitly identifies interim express bus service as a precursor to HCT investments) as well as the 1976 Memorandum Agreement for I–90. Concurrent with the adoption of the *Regional Transit Long-Range Vision*, the Sound Transit Board identified the I–90 corridor as a potential future light rail corridor.

Starting in 1998, WSDOT and Sound Transit served as co-leads on the *Trans-Lake Washington Study*, which identified a set of solutions to improve transportation across and/or around Lake Washington (WSDOT and Sound Transit, 2002). As part of this study, a 47-member study committee (composed of cities, public agencies, businesses, and neighborhood and advocacy groups) reaffirmed earlier decisions that had identified I–90 as the first priority for crossing Lake Washington with HCT.

As part of the implementation of Sound Move, in 2004 WSDOT, Sound Transit, and the Federal Highway Administration (FHWA) collaborated on the I–90 Two-Way Transit and HOV Operations Project. Extensive public outreach and coordination with local jurisdictions occurred during the conceptual design and environmental phase of the project, from 1998 to 2004. The Final EIS for the I–90 Two-Way Transit and HOV Operations Project was issued in May 2004 (WSDOT and Sound Transit, 2004) with a Record of Decision by FHWA in September 2004 (FHWA, 2004).

EXHIBIT 1-5
History of High-Capacity Transit in the East Corridor

Although HCT was not directly considered as an element of the EIS, the alternatives were analyzed to assess whether the project could accommodate future plans to convert the center roadway to HCT, in accordance with the MA for I–90. The preferred alternative, known as R-8A, will narrow the outer roadway lanes and shoulders in order to add an HOV lane in each direction, while maintaining the current reversible operation in the center roadway (as illustrated in Exhibit 1-6). The project also includes new and reconfigured direct-access HOV on- and off-ramps in Mercer Island and south Bellevue. Construction of I–90 Two-Way Transit and HOV Operations Project was initiated in 2007.

As part of the identification of the preferred alternative for the I–90 Two-Way Transit and HOV Operations Project, the parties to the 1976 Memorandum Agreement for I–90 developed an amendment that identified R-8A (i.e., HOV lanes on the I–90 outer roadways) as the first step towards the ultimate configuration of I–90 with HCT deployed in the center roadway. HCT was defined in the amendment as "a transit system operating in dedicated right-of-way such as light rail, monorail or a substantially equivalent system" (City of Seattle et al., 2004).

1.3.2 Identification of Light Rail as the Preferred Mode

Although alternative HCT transportation modes have been included in previous studies, Sound Transit conducted a series of studies of high-capacity modes for the region, and on I–90 in particular, as part of the update to its Long-Range Plan (Sound Transit, 2005).

At the request of Sound Transit, PSRC prepared an assessment of HCT corridors and technologies (PSRC, 2004). PSRC established a base of fully updated population, employment, and travel demand forecasts to be used in this assessment and in the process to update Sound Transit's Long-Range Plan. Using updated land use and transportation plans as adopted in the regional *VISION 2020* Growth Strategy and Transportation Plan (PSRC, 1995), PSRC found that, after the North Corridor between Downtown Seattle and Northgate, the East Corridor is the highest-priority HCT corridor for development. The study reviewed a range of HCT technologies using updated land-use and population projections for the planned HCT corridors. Bus rapid transit, light rail transit, and monorail were deemed appropriate for the East Corridor.

At approximately the same time, Sound Transit initiated preparation of a supplemental draft and final EIS as part of the process to update the agency's Long-Range Plan. The EIS included analysis of potential HCT projects, including the North, East, and South corridors in the Sound Transit district at a programmatic level (Sound Transit, 2005). An extensive public outreach process was implemented for the preparation of the updated Long-Range Plan and Final EIS.

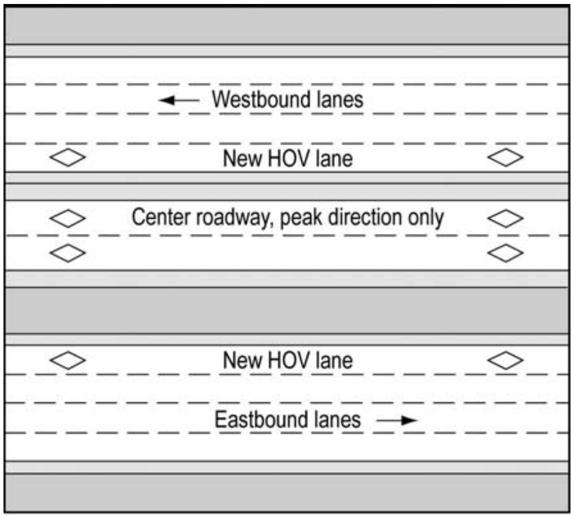

EXHIBIT 1-6
I–90 Two-Way Transit and HOV Operations Project

The Sound Transit Board adopted the updated Long-Range Plan (Sound Transit, 2005), which identified two alternative HCT modes on exclusive right-of-way for further consideration in the I–90/East Corridor between Downtown Seattle, Downtown Bellevue, Overlake, and Redmond: light rail transit and rail-convertible bus rapid transit. The Sound Transit Board also directed staff to complete additional transportation analysis of the I–90 corridor and to present the results of that analysis to the Board for consideration in the development of the next phase of HCT system investments. The following further analyses were completed:

- A full-scale "load test" that simulated light rail operations on the I–90 Homer Hadley Floating Bridge and elevated superstructure and confirmed its capacity to support light rail infrastructure and operations
- A planning-level analysis of the feasibility of the rail expansion joint necessary for construction and operation of light rail on the I–90 floating bridge
- A WSDOT report that detailed future congestion on I–90 and projected traffic impacts on I–90 that would result from growth in traffic volumes (WSDOT, 2006)

- A historical review of the more than 40 years of transportation planning studies and agreements relevant to the I–90 corridor between the Eastside and Seattle (Sound Transit, 2006)

Based on the results of the analyses described above and the technical reports and issue papers on alternative HCT modes, the Sound Transit Board, on July 13, 2006, identified light rail as the preferred HCT transportation mode for the East Corridor (Seattle to Bellevue to Redmond via I–90).

The Sound Transit Board identified light rail because it provides the benefits of operating in an exclusive right-of-way separated from general-purpose and HOV traffic. These benefits include increased reliability and predictability, shorter travel times, and higher ridership compared to nonexclusive HCT modes. Light rail in the East Corridor would use the same technology as the Central Link line and build on that investment. It would provide a higher level of system integration by interlining directly with the Central Link line and providing a direct ride between the Eastside, Downtown Seattle, and the North Corridor stations, including Capitol Hill, University of Washington, and Northgate. Light rail provides the highest level of ridership and the shortest travel times of all technologies evaluated in the corridor.

In July 2008, the Sound Transit Board adopted Sound Transit 2: A Mass Transit Guide, the Regional Transit System Plan for Central Puget Sound (ST2), also known as the Mass Transit Expansion proposal. ST2 is a package of HCT investments in the regional transit system and includes the East Link Light Rail Transit Project. ST2 was approved by the voters in November 2008.

1.4 East Link Project Planning Goals and Objectives

Based on the project purpose, Sound Transit developed evaluation criteria. Sound Transit applied the following goals and objectives in evaluating potential alternatives for the East Link Project. These goals and objectives uphold Sound Transit's legislative mandate to meet public transportation and mobility needs for HCT infrastructure while also being a responsible steward of the environment and being considerate of affected agencies and community members when planning a fiscally responsible project.

1. Transportation goal: Improve transit mobility in the East Link Corridor.
   a. Improve the quality of transit service.
   b. Increase transit accessibility.
   c. Maximize East Link ridership.
2. Environmental goal: Preserve environmental quality in the corridor.
   a. Minimize potential adverse operating impacts on the natural and built environment.
   b. Minimize potential adverse construction. impacts on the natural and built environment.
3. Land use goal: Support regional and local land use goals and objectives.
   a. Support adopted land use and transportation plans.
4. Implementation goal: Minimize risk in the corridor.
   a. Enhance stakeholder and community support.
   b. Design system to reduce construction risk.
5. Financial goal: Provide a financially feasible solution.
   a. Build a system within project budget.
   b. Build a system that can be operated and maintained within available revenue.
   c. Build a system that is cost-effective.

Chapter 2

Alternatives Considered

2.1 Introduction

This chapter describes the alternatives and how they were developed for study in this Final Environmental Impact Statement (EIS). The 2008 Draft EIS evaluated a No Build Alternative and 19 build alternatives within five segments (Segments A to E) for an approximately 18-mile extension of the Link light rail system, from Downtown Seattle to Redmond across the Interstate 90 (I-90) bridge. Since the 2008 Draft EIS was published, the Sound Transit Board has reviewed public and agency comments; added five additional alternatives and some design options to existing alternatives, most of which were analyzed in the 2010 Supplemental Draft EIS (SDEIS); and identified and refined the preferred alternatives for each segment. In response to the SDEIS, additional design options have been included and analyzed in this Final EIS.

The alternatives described here meet the East Link Project purpose and need and include alternatives reviewed as part of the environmental review process as well as those eliminated from consideration.

The evaluation processes that were used comply with guidelines of the National Environmental Policy Act (NEPA); the Washington State Environmental Policy Act (SEPA); and the Safe, Accountable, Flexible, and Efficient Transportation Equity Act—A Legacy for Users (SAFETEA-LU).

The proposed project consists of constructing and operating an approximately 18-mile light rail system known as East Link. This system would connect with Sound Transit's Central Link at the International District/Chinatown Station, and it then would travel east across Lake Washington via I–90 to Mercer Island, Downtown Bellevue, and Bel-Red/Overlake, terminating in Downtown Redmond. Exhibit 2-1 shows the five project segments and the 24 alternative routes with the proposed stations that are considered for detailed environmental review in this Final EIS. A No Build Alternative is also included to describe how the transportation system would operate if the proposed project were not built, thus serving to compare effects of the build alternatives.

EXHIBIT 2-1
East Link Project Segments and Alternatives

The remainder of this chapter is organized into the following subsections:

- 2.2 Alternative Development and Public Scoping Process
- 2.3 Project Alternatives
- 2.4 Overview of Construction Approach
- 2.5 Environmental Commitments
- 2.6 Estimated Projects Costs and Funding
- 2.7 Next Steps and Schedule

2.2 Alternative Development and Public Scoping Process

As stated in Chapter 1, the East Link Project and the alternatives considered in this document build on the conclusions of previous planning, studies, and public involvement processes dating back to the mid-1960s. In particular, the Sound Transit Board made the following major decisions after extensive evaluation and review with agencies and the public before beginning this EIS process:

- Regional high-capacity transit (HCT) to the Eastside via I–90 is necessary.
- Light rail is the selected HCT technology for the I-90/East Corridor connecting Seattle, Mercer Island, Bellevue, Overlake, and Redmond.

Sound Transit's light rail alternatives development process for this Final EIS included the following steps:

- Identifying feasible alternatives
- Obtaining scoping comments on alternatives
- Conducting a detailed evaluation of refined alternatives
- Receiving input on the Draft EIS and SDEIS alternatives and responding with modifications and new alternatives for analysis

For evaluation purposes, the East Link study area was divided into five segments along distinct geographic boundaries (see Exhibit 2-1). The five segments are as follows:

- **Segment A, Interstate-90,** travels from the Downtown Seattle Transit Tunnel (where the East Link Project would connect to the Central Link light rail system) to South Bellevue, where I–90 touches land in Bellevue.
- **Segment B, South Bellevue**, travels from where I–90 touches land in Bellevue to SE 6th Street, including the south boundary of Surrey Downs Park.
- **Segment C, Downtown Bellevue,** travels from SE 6th Street north to NE 12th Street, encompassing Downtown Bellevue and the area east of I-405 to the former BNSF Railway corridor.
- **Segment D, Bel-Red/Overlake,** travels from Downtown Bellevue (from the former BNSF Railway corridor or NE 12th Street) to the Overlake Transit Center at the intersection of NE 40th Street and State Route 520 (SR 520).
- **Segment E, Downtown Redmond,** travels from the Overlake Transit Center to Downtown Redmond, with three potential project terminus locations.

The alternative evaluation process was also informed by an Inter-Agency Team that included the Washington State Department of Transportation (WSDOT); U.S. Army Corps of Engineers (USACE); Federal Transit Administration (FTA); Federal Highway Administration (FHWA); Cities of Seattle, Mercer Island, Bellevue, and Redmond; and King County. In addition, Sound Transit attended and presented information about East Link at neighborhood organizations, stakeholder gatherings, and upon request, city council and other board meetings. Refer to Appendix B for more detail.

2.2.1 Criteria for Evaluation

The Sound Transit evaluation criteria were designed to satisfy the following project planning goals and supporting objectives as directed in the East Link Project purpose and need (see Chapter 1):

- Transportation goal: Improve transit mobility in the East Link corridor.
  - Maximize East Link ridership.
  - Improve the quality of transit service.
  - Increase transit accessibility.
- Environmental goal: Preserve environmental quality.
  - Minimize potential adverse operating impacts on the natural and built environments.
  - Minimize potential adverse construction impacts on the natural and built environments.
- Land use goal: Support regional and local land use goals and objectives.
  - Support adopted land use and transportation plans.

- Implementation goal: Minimize risk.
  - Design system to reduce construction risk.
  - Enhance stakeholder and community support.
- Financial goal: Provide a financially feasible solution.
  - Build a system within project budget.
  - Build a system that can be operated and maintained with available revenue.
  - Build a system that is cost-effective.

2.2.2 Draft EIS Alternatives Identification

To identify the most promising alternatives to propose during the public scoping process, Sound Transit developed 36 preliminary alternatives for the East Corridor between Seattle and the East Link growth centers of Bellevue, Overlake, and Downtown Redmond. In developing the preliminary alternatives, Sound Transit reviewed past planning studies in the corridor and consulted with state, federal, and local agencies in the corridor.

Segment A included only the Interstate 90 Alternative (A1). Of the 35 alternatives in Segments B through E, Sound Transit, in consultation with the Inter-Agency Team, eliminated 9 alternatives based on the initial analysis because of ridership, cost, construction risk, and environmental impacts. Sound Transit recorded this process in *East Link Alternatives Evaluation Report, Seattle to Bellevue to Redmond* (Sound Transit, 2006c).

Sound Transit advanced 27 alternatives and 5 potential maintenance facility locations for further evaluation. Sound Transit summarized the results of the evaluation in *Sound Transit Board Briefing Book, Light Rail Alternatives* (Sound Transit, 2006b), which was presented to the Sound Transit Board and posted on the project website (www.soundtransit.org). This evaluation highlighted the results in the five comparative areas for all alternatives:

- **Ridership:** Additional systemwide boardings from adding East Link to Central Link were calculated.
- **Environmental Impacts:** Impacts were compared for relocations and impacts associated with parks, historic properties, traffic, noise, visual resources, ecology, and removal of parking and lanes, and construction disturbances on adjacent properties.
- **Markets Served:** Markets served are potential station areas with concentrations of employees and/or residents.
- **Construction Risk:** Risks were compared against an average risk of geologic and utilities constraints.
- **Cost:** The lowest cost alternatives in each segment were compared.

Four maintenance facility sites were identified in Segment D and one in Segment E using the criteria of compatible land use zoning, relatively flat areas of approximately 15 acres, and convenient access to the light rail vehicles and tracks.

2.2.3 NEPA and SEPA Scoping Process

The FTA and Sound Transit held a public scoping and comment period to officially initiate the NEPA and SEPA EIS process. The scoping period took place from September 1 to October 2, 2006. Sound Transit invited city and county agencies; affected tribes; regional, state, and federal agencies; interest groups; businesses; affected communities; individuals; and the public to comment on the proposed routes and stations, the environmental resources to be evaluated, and the project's preliminary Purpose and Need Statement. The public and agencies were asked to identify areas of concern, opportunities, and stakeholder interests to be further addressed in the subsequent EIS.

During the scoping period, Sound Transit hosted four public scoping meetings and one scoping meeting for agencies and tribes. The public meetings were held in Seattle, Mercer Island, Bellevue, and Redmond. Oral and written comments were accepted. In addition, the public submitted comments directly by mail and email. Details of the scoping and outreach activities can be found in Section B.4 of Appendix B, Public Involvement and Agency Coordination.

Following this process, on December 14, 2006, the Sound Transit Board identified the alternatives to be evaluated in the Draft EIS. In December 2008, Sound Transit, WSDOT, and FTA published the East Link Project Draft EIS, which evaluated a No Build Alternative and 19 build alternatives.

2.2.4 Supplemental Draft EIS Alternative Identification

After the 2008 Draft EIS was published, the Sound Transit Board reviewed public and agency comments, developed and evaluated new alternatives and design modifications, identified the preferred alternatives for each segment, and then revised the preferred alternatives while directing staff to include more alternatives for study. After the 2008 Draft EIS was published, the City of Bellevue proposed multiple new alternatives and design modifications. Sound Transit has considered each of them, and some of the alternatives have been evaluated in joint studies with the City of Bellevue or other technical reviews.

New alternatives were added to Segments B and C, and design modifications to alternatives previously studied in the Draft EIS were added in Segments B, C, D, and E. Sound Transit published the SDEIS in November 2010 to review the new alternatives and design modifications to existing alternatives that could result in substantial impacts not disclosed in the 2008 Draft EIS.

To help develop the SDEIS, Sound Transit received input through the public process associated with three studies for project elements in Bellevue: the *Downtown Bellevue Light Rail Alternatives Concept Design Report* (Sound Transit and City of Bellevue, 2010a); the *112th Avenue Design Options Concept Design Report* (Sound Transit and City of Bellevue, 2010b); and the *Evaluation of Hospital Station Options* (Sound Transit and City of Bellevue, 2010c). Sound Transit and the City of Bellevue cooperatively developed each study. Each study can be found in Appendix K of this Final EIS or found at http://www.soundtransit.org. Additionally, these studies are summarized in Appendix B, Public Involvement and Agency Coordination. The City of Redmond also held workshops and community outreach meetings that helped further define modifications to Segment D and E alternatives.

The *Downtown Bellevue Concept Design Report* explored new at-grade and grade-separated alternatives in Downtown Bellevue, emphasizing traffic flow and cost trade-offs. The report evaluated six alternatives: two from the 2008 Draft EIS and four new alternatives; all new downtown alternatives studied were included in the SDEIS. Next, the Hospital Station and the 112th Avenue Design Options were explored with extensive public involvement from the community and interested stakeholders. This process reviewed three new locations for the Hospital Station, with optional access points to the hospital district, in addition to the one from the 2008 Draft EIS; the location from the 2008 Draft EIS was chosen to be carried forward. Along 112th Avenue SE, six at-grade and retained-cut profiles traveling in the center and on the east and west sides of 112th Avenue SE were studied. Information from the study and input from the community led the Sound Transit Board to identify the preferred alternative as the west side-running alignment along 112th Avenue SE north of SE 6th Street, which was considered in the SDEIS.

In July 2010, the City of Bellevue requested that the Sound Transit Board consider new modifications to the BNSF Alternative (B7) and the *Preferred 110th NE Tunnel Alternative (C9T)*, including a new South Bellevue Station adjacent to I-90 and a NE 2nd Street portal for the *Preferred Alternative C9T* tunnel. After the SDEIS was published, the City initiated a conceptual design and screening-level evaluation of these options or modifications to Alternative B7, referred to as B7-Revised (B7R). A brief description of these options is provided following Segment C in Section 2.2.5.1 of this chapter, and the results of the City's study are summarized in Section 7.6 of Chapter 7. The City of Bellevue's B7-Revised Interim Analysis Report (May 2011) can be found in Appendix K of this Final EIS.

2.2.5 Alternatives Eliminated

2.2.5.1 Alternatives Eliminated During Screening

After reviewing evaluation results and public and agency comments, the Sound Transit Board in December 2006 identified the alternatives to be analyzed in the Draft EIS. The Board eliminated eight alternatives and one maintenance facility site from further consideration, leaving 19 alternatives and 4 maintenance sites for review in the Draft EIS. The process of elimination is discussed below.

Segment B

In Segment B, three alternatives were eliminated, two of which traveled east along the south edge of Mercer Slough Nature Park and then turned north along the east boundary of the park adjacent to 118th Avenue SE. North of the park, the two alternatives diverged to follow different roadways. Sound Transit eliminated these alternatives because they would result in the highest environmental impacts along the Mercer Slough Nature Park and wetland areas, without providing any additional benefit compared to a remaining parallel alternative with lesser park impacts. The third alternative eliminated in Segment B had unnecessary out-of direction travel, resulting in higher costs and inefficiencies, without higher ridership than other alternatives in Segment B. This alternative traveled east, across the south edge of the Mercer Slough Nature Park, paralleling north of I-90, and turned north inside the former BNSF Railway corridor. This alternative then transitioned to parallel I-405, where the former BNSF Railway corridor continues east across I-405. At SE 8th Street, this alternative returned west to 112th Avenue SE, where it continued north.

Segment C

In Segment C, two alternatives were eliminated because of lack of available right-of-way at NE 7th Street. One alternative traveled along 110th Avenue NE and turned to cross over I-405 at approximately NE 7th Street, where there was thought to be inadequate separation between Meydenbauer Center and the newly constructed The Shops at Bravern. The other alternative followed 112th Avenue and transitioned to 110th Avenue NE via NE 4th Street before turning east at NE 7th Street. Again, there would be inadequate separation between Meydenbauer Center and the Shops at Bravern.

Segment D

Two alternatives in Segment D were found to result in excessive impacts along Bel-Red Road. One alternative traveled the length of Bel-Red Road from 124th to 152nd Avenue NE. The other traveled along NE 16th Street, a new planned roadway, then merged onto Bel-Red Road at 140th Avenue NE and continued to 152nd Avenue NE. Placing light rail in the median and widening the Bel-Red Road right-of-way would result in higher impacts on adjacent uses and greater construction and other environmental impacts. None of the remaining alternatives would travel along Bel-Red Road.

Segment E

Only one alternative was eliminated in Segment E. Segment E alternatives diverge from the same route at the SR 520 interchange with West Lake Sammamish Parkway. The alternative that was eliminated followed the south side of Bear Creek Parkway and traveled along several minor arterials up to the Bear Creek Park-and-Ride. This alternative was eliminated because it would have excessive impacts on ecosystems, parks, and traffic compared with other alternatives in Segment E. In addition, the Bear Creek Park-and-Ride location would present circulation and accessibility constraints related to adding a large terminus parking garage.

Maintenance Facilities

Five maintenance facility sites were considered, and only one, located near 136th Street NE in Segment D, was eliminated. Its location would have high environmental impacts and would limit transit-oriented development potential near a potential station.

2.2.5.2 Alternatives Eliminated after the Draft EIS and SDEIS

Comments on the 2008 Draft EIS resulted in a number of suggestions of new or previously studied alternatives, most of which have been eliminated from consideration for engineering, cost, and/or environmental issues. Specific responses to each letter and the suggestions are provided in Appendix J, Public and Agency Comments and Responses.

The *112th Avenue Light Rail Options Concept Design Report* evaluated six alternatives for connecting *Preferred 112th SE Modified Alternative (B2M)* with either *Preferred 108th NE At-Grade Alternative (C11A)* or *Preferred 110th NE Tunnel Alternative (C9T)*, with a portal at either Main Street or NE 2nd Street. Those alternatives that were not carried forward were eliminated primarily due to noise, transportation, and/or construction impacts; cost; and/or community input.

Sound Transit reviewed four Hospital Station options with the City of Bellevue and decided to carry forward the original alternative location based on criteria of optimizing station spacing, visibility, accessibility, and cost.

The City of Bellevue also requested that Sound Transit examine two design modifications to the route east of the Bellevue Transit Center Station and east of I-405: (1) moving the route along NE 6th Street further south and (2) crossing underneath NE 8th Street east of I-405 before entering the Hospital Station. Both requests would affect the *Preferred Alternatives C11A* and *C9T* routes similarly. Shifting the route to the south side of NE 6th Street is not evaluated further because it would not reduce costs and would result in greater impacts on Bellevue City Hall and the King County Metro site redevelopment (located on the vacant lot next to the city hall building); it would require longer span structures over I-405 and 116th Avenue NE; and it would acquire an additional office building. Crossing underneath NE 8th Street is not evaluated further because it would increase costs by adding a tunnel and would push the Hospital Station location further north near NE 12th Street. This station location would have less desirable access, as demonstrated in the *Evaluation of Hospital Station Options* study and, due to the tunnel, would be approximately 30 feet below grade, resulting in higher cost and lower accessibility to riders.

Comments on the 2010 SDEIS resulted in a number of suggested modifications to existing alternatives in order to avoid impacts to specific properties; these have not been included in the Final EIS because they generally would result in greater impacts to different properties, including parks, and potentially would increase other impact categories, such as noise, visual, and traffic. The East Link Project Final EIS addresses each suggestion in the response to comments (Appendix J).

2.3 Project Alternatives

Following the alternatives evaluation process, Sound Transit identified a No Build Alternative, 24 build alternatives, and 4 maintenance facility alternatives to carry forward to analyze in this Final EIS. This section describes each of these alternatives and the key project components that help to distinguish the alternatives. The *Preferred Alternative* is called out in italics to indicate the current preference identified by the Sound Transit Board. Identifying a *Preferred Alternative* in this Final EIS is a statement of the Board's current intent based on the input and analysis to date; it is not a final decision. Exhibit 2-2 illustrates the preferred alternatives in all segments:

- Segment A: *Preferred Interstate 90 Alternative (A1)*
- Segment B: *Preferred 112th SE Modified Alternative (B2M)*
- Segment C: *Preferred 108th NE At-Grade Alternative (C11A)* and *Preferred 110th NE Tunnel Alternative (C9T)*
- Segment D: *Preferred NE 16th At-Grade Alternative (D2A)*
- Segment E: *Preferred Marymoor Alternative (E2)*

Sound Transit 2 Plan (ST2) provides funding for an at-grade or elevated alternative in Downtown Bellevue (Segment C); the Sound Transit Board would require additional funding sources in order to select a tunnel alternative in this segment. The Sound Transit Board identified two preferred alternatives in Segment C in April 2010: *Preferred 108th NE At-Grade Alternative (C11A)* and *Preferred 110th NE Tunnel Alternative (C9T)*. *Preferred Tunnel Alternative C9T* is preferred based on a term sheet (a preliminary agreement) executed between Sound Transit and the City of Bellevue related to finding additional funding sources and scope reductions that would reduce the affordability gap for this tunnel alternative. *Preferred Alternative C11A* is preferred if additional funding and scope reductions cannot be found to afford the tunnel.

Environmental review and preliminary engineering are funded for the portion of the East Link Project from the Overlake Transit Center Station to Downtown Redmond. While the final length and configuration of the constructed project would depend on project funding, final project design, track profiles, and project costs, this Final EIS covers the entire Seattle to Redmond East Link Project corridor. A separately bound document, Appendix G1, provides the detailed design drawings for each alternative.

The East Link Project might be constructed in phases, depending on available funding and other factors. Sound Transit anticipates that any station including and east of the Hospital Station could be considered an interim terminus station. The minimum planned project would be to open East Link from Seattle to the Hospital Station in Bellevue (Segments A through C).

2.3.1 No Build Alternative

The No Build Alternative represents the transportation system and environment as they would exist without the proposed project. The No Build Alternative provides a baseline condition for comparing impacts of the build alternatives and includes two future transportation forecast years, 2020 and 2030.

The No Build Alternative includes a variety of projects, funding packages, and proposals in the central Puget Sound region. The projects primarily consist of funded or committed roadway and transit actions by state, regional, and local agencies combined with other projects that are considered likely to be implemented based on approval and committed funding. The No Build Alternative includes completing the express bus, high-occupancy vehicle (HOV), and Transportation System Management projects described in Sound Move (Sound Transit, 1996) and also includes the Rapid Ride and other transit enhancements in the King County *TransitNow Program* (King County Metro, 2006). Table 2-1 summarizes roadway and transit projects that are included in the No Build Alternative. Appendix H1, *Transportation Technical Report* (Appendix A), details major projects assumed as part of this No Build Alternative.

For the transportation analysis, there are two No Build Alternatives related to implementing the I–90 Two-Way Transit and HOV Operations Project (also referred to as the R-8A Project). The two variations in the No Build Alternative lie in implementing the I–90 Two-Way Transit and HOV Operations Project from Bellevue to Mercer Island to Seattle. Exhibit 2-3 illustrates how that project has been separated into three stages for funding purposes and describes what is included in each phase.

The East Link Project would dedicate the I-90 center roadway for light rail use as stipulated in the 1976 Memorandum Agreement (and as amended in 2004; WSDOT, 2004) among Seattle, Mercer Island, Bellevue, King County Metro, and WSDOT. Today, the reversible center roadway is dedicated as HOV lanes traveling in the peak direction (Exhibit 2-4), and the outer roadways are general-purpose lanes. HOV lanes are being built on the outer roadways in three stages (Exhibit 2-5) so that HOVs can travel in both directions any time of the day. Funding for Stage 3 of the I-90 Two-Way Transit and HOV Operations Project is included in ST2. With ST2 approved, Sound Transit intends to work with WSDOT to complete Stage 3 and then close the center roadway for light rail conversion.

In other words, the center roadway might close in order to construct the light rail project immediately after the HOV lanes on the outer roadway are completed, and the new HOV lanes in the outer roadway would never operate in conjunction with the center roadway. As a result, the No Build Alternative was analyzed with and without Stage 3 completion.

Without Stage 3, HOV and transit travel between Mercer Island and Seattle would be restricted to the center reversible lanes in the peak direction only (i.e., westbound in the morning and eastbound in the evening). If Stage 3 were implemented, however, and began operating in conjunction with the center roadway before East Link construction begins, then both outer lanes of I-90 and the center reversible lanes would be available to transit and HOV. This variation in the lane configuration would only influence vehicle movements on I-90 and connecting transportation facilities.

2.3.2 Build Alternatives

Light rail is a conventional term for urban electric rail systems that have the flexibility to operate along an exclusive right-of-way at ground level, on elevated structures, in subways, or in streets. Sound Transit plans for light rail consist of electrically powered, low-floor, low-platform trains of up to four cars, with a total length of approximately 380 feet (90 feet per car, 96.5 feet per car with couplers), running on steel rails. The vehicles can carry as many as 200 passengers per car in the typical light rail car shown in Exhibit 2-6. East Link light rail would operate at speeds up to 55 miles per hour (mph) in a dedicated right-of-way and would generally not be constrained by congestion or accidents. The dedicated right-of-way might be in public roadway or in existing railroad or acquired right-of-way.

The build alternatives are made up of a range of light rail routes and stations, with and without adjoining park-and-ride facilities. Maintenance facility alternatives are evaluated separately from the alternative routes and stations. Each build alternative is designed as a double-track rail system to accommodate planned project operational needs for uninterrupted light rail movement. The length of the entire East Link Project would vary between 17 and 19 miles, with up to 19 stations, depending on how the alternatives are combined. This section describes the

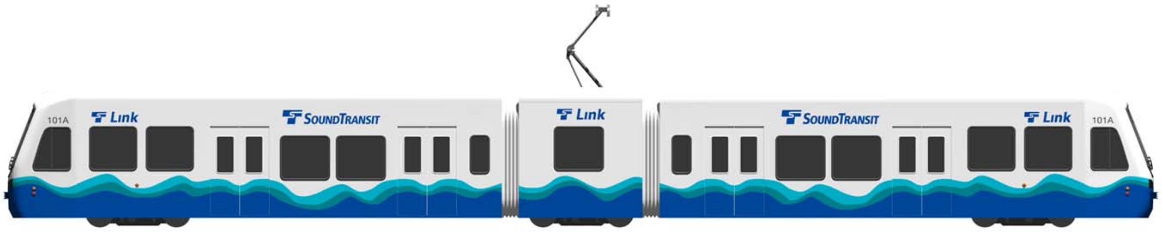

EXHIBIT 2-6
Typical Light Rail Car

alternative routes and stations by segment. The alternatives have been developed to a conceptual engineering level of design (i.e., approximately 5 percent). Section 2.3.3 describes the maintenance facilities, and detailed drawings are included in Appendix G1, Conceptual Design Drawings.

2.3.2.1 Components of Alternatives

This section describes key components, such as the rail and station profile, to assist the reader in the understanding the alternatives. Other aspects of the project, including capital equipment and project operations, are described in Section 2.4.

The proposed route and station alternatives vary in profile as traveling at-grade (sometimes a retained cut or a retained fill), in an elevated configuration, or in a tunnel. Maximum allowable grades for light rail are typically 5 to 6 percent. Because of the conditions along the corridor, the East Link Project is largely elevated or at-grade; however, tunnel alternatives were also considered in Downtown Bellevue (Segment C). At-grade operation is typically less costly, although each profile type has usefulness, as discussed in the following subsections.

At-Grade Profile

Light rail operating at-grade is best suited in areas where the grade is 5 to 6 percent or less and where there is adequate room within reserved street rights-of-way or off-street corridors. At-grade operation works well with a moderate number of riders and train frequencies as often as every 4 minutes. Where located within a street right-of-way, East Link at-grade routes travel either in the median or along the side of existing roadways (Exhibit 2-7) and operate through intersections with advance signal detection and prioritization.

Retained Cuts and Retained Fills

A variation of the at-grade profile is a retained cut or a retained fill. With a retained cut the trackway is cut into the ground with a retaining wall on one or both sides (Exhibit 2-8). With a retained fill the trackway is built up above the ground surface with a retaining wall on one or both sides. Exhibits 2-9 and 2-10 show possible retained fill profiles. Portions of the routes might involve retained cut or retained fill to meet train operation grade requirements or to separate the grade under heavily traveled roadways.

Elevated Profile

Light rail on elevated structures works well where the system must be grade-separated to cross over geographic or physical barriers and accommodate higher train frequencies and where at-grade trackway might not be appropriate for a surface corridor. Transitions between at-grade and elevated profiles are typically compacted fill support. An elevated profile must have a minimum clearance of about 16.5 feet near roadways, but topography and other consideration might result in a profile as high as 50 feet or more. Pier supports are typically approximately 10 feet by 10 feet square at the ground, although the support structure below the ground might be wider. Just as for at-grade routes, the elevated guideway can travel either in the median of existing roadways (Exhibit 2-11), along the side of the roadway (Exhibit 2-12), or in off-street corridors.

Tunnels

Tunnels might be used where slopes are steep (more than 5 to 6 percent), physical barriers must be crossed, right-of-way is inadequate for at-grade or elevated profiles, the density of homes and businesses is high, and/or ridership and resulting train frequencies would be so high as to make street-level operations impractical. They are also appropriate where major ridership areas cannot be served in another way. There are substantially greater costs and risks with building tunnels. The two most common construction methods are cut-and-cover or bored tunnels. Cut-and-cover construction is built from the surface while bored (or mined) tunnels are constructed with no surface disturbance beyond entering and exiting the tunnel portals. The bored method is typically the most expensive. A cut-and-cover box and bored tunnel are shown in Exhibits 2-13 and 2-14.

Stations

Stations are designed according to the alternative profile. Depending on the location, stations can be designed with center or side platforms. Center platforms allow passengers to access trains going in opposite directions from the same platform. Side platforms, much like a sidewalk on either side of a roadway, require the riders to cross over or under the tracks to access trains in the opposite direction. A station is typically 400 feet long to accommodate a four-car train but varies in width depending on the location of the platform and the profile.

East Link stations would include pedestrian, bicycle, and bus access (with one exception) and may include paratransit access. All stations are Americans with Disabilities Act (ADA) accessible. In some cases, automotive access including park-and-ride lots and automobile drop off would be provided. Exhibit 2-15 illustrates four typical station designs: at-grade, elevated side platform, elevated center platform, and a tunnel station. The size of each station is determined by the site-specific access and parking requirements.

EXHIBIT 2-15
Typical Station Designs

East Link stations would be designed to meet all local and federal accessibility requirements. At-grade stations would have passenger access walkways and ramps. Any elevated or tunnel station would be furnished with stairs, elevators, and, in some cases, escalators. Each station would have ticket vending machines, closed-circuit television, public address, emergency phones, and variable message signage. Additionally, tunnel stations would have systems that monitor and control ventilation and fire/life/safety functions.

Interim Termini

The East Link Project might be constructed in phases, depending on available funding and other factors. Sound Transit anticipates that any station including and east of the Hospital Station could be considered an interim terminus station. The minimum planned project would be to open East Link from Seattle to the Hospital Station in Bellevue (Segments A through C).

If the East Link Project were built in phases, a station in Segment C or D would be selected as the interim terminus station. The Hospital or Ashwood/Hospital Station in Segment C or any Segment D station could serve as an interim terminus. The Overlake Transit Center Station in Segment D is identified as an interim terminus in ST2, because funding for constructing Segment E is not included in the plan. With any interim terminus station, a storage or tail track could be built beyond the station. The preferred location is a storage track in the former BNSF Railway north of the Hospital Station. If such a feature were built at an interim terminus station, then the project might also include parking for operators and office and storage space for light maintenance activities, such as cleaning interiors of vehicles.

Railbanked Corridors

Several of the build alternatives would use portions of the former BNSF Railway corridor. In 2008, the BNSF Railway Company filed a Notice of Interim Trail Use or Abandonment (NITU) with the Surface Transportation Board. This filing "railbanked" the right-of-way for interim trail use and keeps the right-of-way available for the reactivation of freight rail service. In addition to being the "trail sponsor" under the NITU, King County owns a trail easement over the former BNSF Railway right-of-way. In 2009, the Port of Seattle acquired the former BNSF Railway right-of-way from Snohomish to north Renton, including a spur from Woodinville to Redmond. The Port entered into a Memorandum of Understanding (MOU) with King County, the City of Redmond, Sound Transit, Puget Sound Energy, and the Cascade Water Alliance with regard to the Port's sale to the other parties of the former BNSF Railway right-of-way within King County. Sound Transit is in the process of acquiring 1.1 miles of this corridor in Segments C and D as well as an easement in other portions of the corridor potentially used by East Link.

Sound Transit and the Puget Sound Regional Council (PSRC) have studied the feasibility of commuter rail service in the former BNSF Railway corridor. This study, published by Sound Transit in 2008, found that operating commuter/passenger rail in the former BNSF Railway corridor is feasible although a variety of capital improvements would be needed to accommodate higher speeds and to improve the safety of the track, structures, and roadway crossings in the corridor. The study also determined that a pedestrian/bicycle trail could also fit within the existing right-of-way throughout much of the corridor; however, in some locations, property acquisition would be required to accommodate commuter/passenger rail and a trail. Sound Transit is working with the MOU parties to plan for using the former BNSF Railway corridor while protecting the interim trail use and possible reactivation for freight rail. The corridor can accommodate both the trail (or a reactivated freight rail service) and the light rail route in most places, with some areas requiring a small right-of-way acquisition.

Numbering of East Link Alternatives

East Link Project alternatives are designated by either two or three characters: the segment letter (A, B, C, D, E), the number of the alternative, and, sometimes, a descriptive indicator consisting of A for at-grade, E for elevated, or T for tunnel. The letter M signifies "modified" from a previous Draft EIS alternative. For example, B2M indicates the second alternative in Segment B, and that it has been modified since the 2008 Draft EIS. C9A indicates the ninth alternative in Segment in C, and that it is an at-grade profile. A break in the numeric sequencing for the alternatives indicates that a previous alternative was eliminated in the alternative development process (see Section 2.2.5).

2.3.2.2 Description of Alternatives

The route and station alternatives are described below, and their characteristics are summarized in Tables 2-2 and 2-3. Exhibits 2-16 to 2-20 show the alternatives by segment. The four maintenance facility alternative sites located in Segments D and E are described in Section 2.3.3 and in Exhibits 2-19 and 2-20. The alternatives are designated by letters and numbers that describe their location and nature, as described in the text box on this page. The types of tunnels for each alternative are discussed in Section 2.4.6, and stations are listed in the following alternative descriptions and summarized in Table 2-3.

TABLE 2-2
Characteristics of Light Rail Alternatives

Alternative		Segment Length (miles)[a]	Segment Travel Time (minutes: seconds)[a]	Number of Stations	Stations

Segment D, Bel-Red/Overlake					
120th[b]	*Preferred Alternative D2A* and Alternatives D2E and D3	Approximately NE 15th Street at 122nd Avenue NE	At-grade or elevated	None	300 (surface) (*D2A* only)
130th[b]	*Preferred Alternative D2A* and Alternatives D2E and D3	Approximately NE 15th Street at 130th Avenue NE	At-grade or elevated	None	300 (surface)
Overlake Village[b]	*Preferred Alternative D2A* and Alternatives D2E, D3, and D5	Depending on the alternative, on or near 152nd Avenue NE and near SR 520 or NE 24th Street	At-grade or retained cut	205	205
Overlake Transit Center[b]	*Preferred Alternative D2A* and Alternatives D2E, D3, and D5	NE 40th Street and 156th Avenue NE	At-grade	170	320 (3-story structure)
Segment E, Downtown Redmond					
Downtown Redmond	*Preferred Alternative E2*	Former BNSF Railway west of Leary Way	At-grade	None	None

TABLE 2-3 CONTINUED
Characteristics of Stations

Station Name	Associated Alternative	Location	Station Profile	Park-and-Ride Lot	
				Existing Parking Spaces	Total Parking Spaces (Configuration)
Redmond Town Center[b]	Alternatives E2 - Redmond Transit Center Design Option, E1, and E4	Former BNSF Railway at approximately 166th Avenue NE	At-grade	None	None
SE Redmond	*Preferred Alternative E2* and Alternatives E2 - Redmond Transit Center Design Option, E1, and E4	Southeast of the SR 202 and Redmond Way SR 520 interchange	At-grade or elevated	None	1,400 (5-story structure)
Redmond Transit Center	Alternative E2 - Redmond Transit Center Design Option	161st Avenue NE at NE 83rd Street	At-grade	380	380

Note: Italicized alternatives signify Preferred Alternatives.

[a] This indicates if connecting from Alternative B3, B3 - 114th Extension Design Option, or B7 for *Preferred Alternative C9T* or Alternative C2T, C3T, C4A, C7E, C8E, or C9A. Also, this indicates connecting from *Preferred Alternative B2M* for *Preferred Alternative* C9T as a design option, which would replace the SE 8th Station on *Preferred Alternative B2M*.

[b] Could serve as an interim terminus station for phasing East Link Project development. Three hundred stalls would be provided at either the 130th Station or the 120th Station, but not at both.

Segment A: Interstate 90, *Preferred Interstate 90 Alternative (A1)*

This segment has one alternative, *Preferred Interstate 90 Alternative (A1),* which crosses Lake Washington and connects Seattle and Mercer Island with Segment B, South Bellevue. This alternative has two stations, one in Seattle and one on Mercer Island. Additional information on the proposed stations is provided in Table 2-3. *Preferred Alternative A1* begins in the Downtown Seattle Transit Tunnel at the International District/Chinatown Station where it connects to the Central Link light rail system.

From there, the alternative enters the D2 Bridge and Roadway. The D2 Roadway is a ramp between Downtown Seattle and Rainier Avenue providing HOV access to I–90. Two potential operational options exist for this section of the D2 Roadway; the preferred option is where the roadway would operate as a joint light rail/bus facility with embedded track. The other option would operate light rail exclusively on the D2 Roadway. In both options, nontransit HOV automobiles would be prohibited. The existing Rainier Avenue bus flyer stop would remain on I–90 for either scenario. Joint operations would allow buses to bypass congestion in the I-90 general-purpose lanes during peak periods. Gates and other security devices would prevent nontransit vehicles from entering this segment of the D2 Roadway. Should a vehicle enter the bus queuing area, provisions would be made for the vehicle to exit back into the westbound I-90 mainline lanes (at the Rainier Avenue interchange) or turn around (at 5th Avenue) to leave the area.

Preferred Alternative A1 proceeds in the I–90 center roadway to the Rainier Station east of the existing Rainier Valley Bus Stop. Pedestrian access to the Rainier Station is from Rainier Avenue South via a new retained-cut ramp and from 23rd Avenue South via elevators and escalators/stairs. *Preferred Alternative A1* then passes through the Mount Baker Tunnel, travels in an exclusive right-of-way in the center roadway on the floating bridge and continues to the Mercer Island Station located between 77th and 80th Avenues SE by the existing Mercer Island Park-and-Ride (see Exhibit 2-21 for plan view of East Link on the I-90 bridge). The preferred pedestrian access is from both 77th and 80th Avenues SE. There is an option (not preferred) to construct access from 80th Avenue

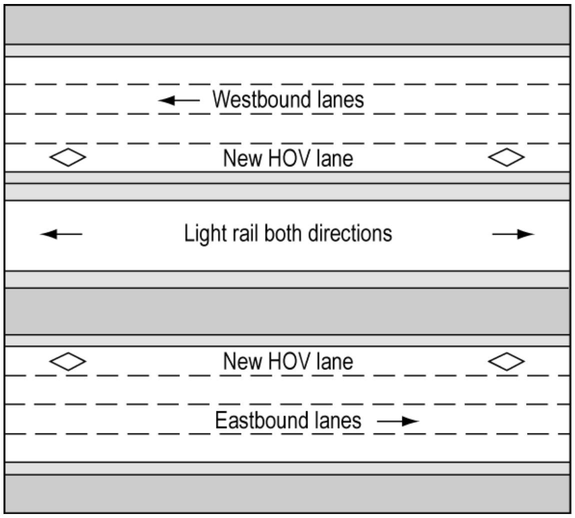

EXHIBIT 2-21
I-90 with *Preferred Alternative A1*

SE along with a new pedestrian bridge over the eastbound lanes of I–90 to the station with direct connection from the Mercer Island Sculpture Garden and Town Center Shopping district (approximately 78th Avenue SE). A portion of the center roadway on the floating bridge would be dedicated to a WSDOT maintenance road to allow continued access to the bridge pontoon hatches. Both the I-90 tunnels and the floating bridge would require modifications to incorporate light rail. Modifications to the tunnels would include adding wall dividers, drainage, and ventilation. To equalize weight on the bridge from installing steel rail, concrete barriers along the south side would be replaced with cable railing, and/or the concrete surface might be made thinner by removing the upper layers. Finally, to accommodate movement of the floating bridge in relation to the fixed approach bridge structure at both ends, a specialized rail expansion joint would be installed on the bridge.

From the Mercer Island Station to Segment B, *Preferred Alternative A1* continues along the I–90 center roadway in exclusive right-of-way. Converting the center roadway to light rail would close the existing ramps that connect the center roadway to the westbound and eastbound general-purpose lanes near the Rainier Avenue South interchange on the west and the East Channel bridge on the east. In addition, the ramps connecting both 77th Avenue SE and Island Crest Way to the center roadway would be closed. *Preferred Alternative A1* would relocate the planned eastbound HOV off-ramp to Mercer Island from 77th Avenue SE to Island Crest Way by connecting the existing eastbound center roadway off-ramp to Island Crest Way with the future eastbound HOV lane, which is part of the I-90 Two-Way Transit and HOV Operations Project. A second option would leave the planned eastbound HOV off-ramp to Mercer Island at 77th Avenue SE. Finally, a third option removes the eastbound HOV off-ramp to Mercer Island altogether. The eastbound I-90 general purpose ramp to 77th Avenue SE and the ramp from Island Crest Way to the westbound I-90 general-purpose lanes would remain open with the project.

Four traction power substations (TPSS) are planned for Segment A, two on the Seattle side and two on Mercer Island. The first TPSS on the Seattle side is located along the D2 Roadway near the intersection of South Norman Street and Poplar Place South. The second TPSS is located at the west end of the I-90 floating bridge. On Mercer Island, the first TPSS is located at the east end of the I-90 floating bridge, adjacent to a WSDOT maintenance facility. The second TPSS on Mercer Island is located near the Shorewood Drive crossing of I-90 (see Exhibit 2-16).

I-90 Floating Bridge Design Considerations

Preferred Alternative A1 has several design considerations regarding the compatibility of light rail with the I-90 floating bridge. The Washington State Legislature Joint Transportation Committee commissioned an independent review team (IRT) to evaluate the bridge analysis. Specific concerns (described below) involve the expansion joints between the approach bridges and the transition spans and between the transition spans and the floating bridge, the additional weight of rail and trains on the bridge pontoons, stray electrical currents, seismic upgrades, installation of light rail components on the bridge, and bridge maintenance changes. The IRT concluded that all issues identified as potentially affecting feasibility can be addressed through project design measures.

Expansion Joints

The I-90 floating bridge includes land-based fixed spans connected by transition spans to the floating midsection of the bridge. The existing traffic expansion joints between the fixed and floating portions of the bridge allow for bridge movements, and the new light rail expansion joints would also need to accommodate these movements. Because this would be the first known example of rail operation on a floating bridge, Sound Transit compared the anticipated movement on the I-90 bridge with the movements of modern passenger rail suspension bridges, since suspension bridges have flexibility in slight up-down and sideways movements, just as water movements have on the floating bridge. This comparison demonstrates that it is feasible to design a light rail track system to accommodate the movements of the I-90 floating bridge. Sound Transit developed a conceptual design for the track expansion joints and will further develop plans for early design and prototyping of the joint, with continued coordination with WSDOT during the design.

Additional East Link Weight

WSDOT and Sound Transit conducted load testing in September 2005. Results of the load test confirmed previous findings that the bridge can be structurally retrofitted to carry the loads associated with the light rail system in addition to general roadway traffic. The additional weight would not change the bridge's ability to remain safe during storm events.

Stray Currents

Stray electrical current from light rail operation could corrode the steel bridge components. The project would include up to three layers of protection: isolating the rail by constructing special insulating systems, installing a stray current collector mat, and potentially upgrading the cathodic protection system. Additionally, the project would place a monitoring system on the bridge to monitor stray current levels.

Seismic Upgrade

Sound Transit would improve the earthquake resistance of the structures in the corridor used by light rail. Structures assumed to be retrofitted include the columns, bridge seats and restrainers for the light rail portions of the D2 Roadway, Rainier Avenue South overcrossing, approach spans to the floating bridge, and the East Channel bridge, using the currently known FHWA/American Association of State Highway Transportation Officials (AASHTO) policies, consistent with WSDOT's own practices for retrofitting existing structures. Retrofits might involve in-water work to improve the earthquake resistance of the floating bridge approach spans and East Channel bridge. The floating bridge is generally not vulnerable to seismic events due to the dampening effect of the lake water.

Light Rail Installation

The rails are typically attached to a bridge by placing them on concrete plinth blocks. These, the overhead catenary poles, and other pieces of rail equipment are normally attached to a bridge deck with mechanical attachments. However, the bridge deck has a dense fabric of reinforcing steel and post-tensioning cable. Therefore, if mechanical attachments are used, it is important to locate this steel to avoid damaging it. Sound Transit has demonstrated that it can locate the steel using the proven method of ground-penetrating radar. Sound Transit would work with WSDOT to determine the most appropriate method for attaching the rail components on the bridge.

Bridge Maintenance

Some maintenance procedures might change with light rail on the bridge. Sound Transit would work with WSDOT to make sure that the bridge can continue to be maintained satisfactorily.

Segment B: South Bellevue Alternatives

Segment B has six alternatives that connect to Downtown Bellevue in Segment C. The alternatives in Segment B have one or two stations at three possible locations: the South Bellevue Station, the SE 8th Station, and the 118th Station. Exhibit 2-17 shows the locations and overall features of the six alternatives, Exhibits 2-22 to 2-28 show details of each alternative, and Table 2-3 provides additional information on the proposed stations.

EXHIBIT 2-27
112th SE Bypass Alternative (B3)

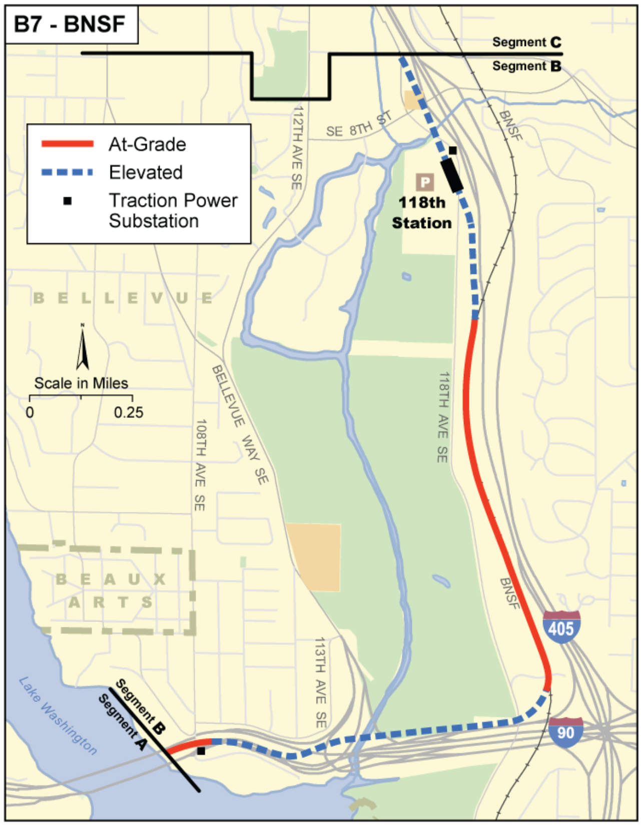

EXHIBIT 2-28
BNSF Alternative (B7)

The Sound Transit Board identified *Preferred 112th SE Modified Alternative (B2M)* as the *Preferred Alternative* in Segment B. This alternative was selected based on technical analysis and input from the community.

Preferred 112th SE Modified Alternative (B2M)
Preferred Alternative B2M (see Exhibits 2-22 and 2-23) is elevated in the I-90 center roadway, crosses over westbound I-90, and continues elevated on the east side of Bellevue Way SE to the South Bellevue Station, located at the current South Bellevue Park-and-Ride; this alternative also maintains the westbound and eastbound I-90 HOV direct access ramps.

The South Bellevue Station includes a parking structure with up to five levels built on the site of the existing South Bellevue Park-and-Ride; however, only three stories would be visible above Bellevue Way SE. After leaving the station, the route transitions to a retained cut on the east side of Bellevue Way within Mercer Slough Nature Park to the intersection of Bellevue Way SE and 112th Avenue SE. In front of the Winters House the route is in a lidded retained cut approximately 170 feet long. From this point, *Preferred Alternative B2M* has two variations that connect to one of the Segment C *Preferred Alternatives*: one provides a connection to the *Preferred 108th NE At-Grade Alternative (C11A)* and one connects with the *Preferred 110th NE Tunnel Alternative (C9T)*. The following describes the two variations:

- When connecting to *Preferred Alternative C11A*, *Preferred Alternative B2M* transitions from a retained cut to at-grade on the east side of 112th Avenue SE. South of SE 15th Street, *Preferred Alternative B2M* crosses the northbound lanes of 112th Avenue SE at a gated crossing and continues north in the center of 112th Avenue SE at-grade until reaching Segment C at SE 6th Street. This variation does not have a SE 8th Station (Exhibit 2-23).
- When connecting to *Preferred Alternative C9T*, *Preferred Alternative B2M* transitions from retained cut to at-grade on the east side of 112th Avenue SE to the at-grade SE 8th Station north of SE 8th Street. If an East Main is selected for C9T, this station would not be built. From there, *Preferred Alternative B2M* remains at-grade until reaching Segment C at SE 6th Street (Exhibit 2-23). This variation of *Preferred Alternative B2M* has a gated crossing (preferred) or an option to close the Bellefield Office Park entrance at SE 15th Street.

For both variations of *Preferred Alternative B2M*, a TPSS is located on the east side of Bellevue Way at SE 30th Street, near the Sweylocken boat launch.

Bellevue Way Alternative (B1)
The Bellevue Way Alternative (B1) (see Exhibit 2-24) travels within the I–90 center roadway and continues in the Bellevue Way SE HOV direct-access ramp under the westbound lanes of I–90 onto Bellevue Way at-grade to the South Bellevue Station and Park-and–Ride; use of the westbound and eastbound HOV access ramps would be eliminated. Alternative B1 travels in the median of Bellevue Way SE up to Segment C at SE 6th Street. The South Bellevue Station includes a four-story parking structure; however, only about two stories appear above the grade of Bellevue Way. To maintain two travel lanes in either direction with light rail in the median, the stretch of Bellevue Way from north of the South Bellevue Station up to SE 6th Street would generally be widened to the west. However, north of the 112th Avenue SE intersection, the widening of Bellevue Way might fluctuate to either side in some locations. There are two TPSSs for B1, one under I–90 where I–90 touches Bellevue and the other near SE 8th Street.

112th SE At-Grade Alternative (B2A)
The 112th SE At-Grade Alternative (B2A) (see Exhibit 2-25) is elevated in the I–90 center roadway, crosses over westbound I–90, and touches down on the east side of Bellevue Way in an elevated profile. With this alternative, the westbound ramp would be

maintained and the eastbound I–90 HOV ramp would either be closed or be kept open by reconstructing the ramp and making other interchange modifications. An elevated station would be located at the South Bellevue Park-and-Ride, with additional parking as provided Alternative B1. After leaving the station, Alternative B2A transitions to at-grade in the median of Bellevue Way, turning into the median of 112th Avenue SE and extending to SE 6th Street.

Additional right-of-way would be required along the east side of Bellevue Way SE, both north and south of the Winters House, as well as across from the Winters House on the west side of the road. Also, 112th Avenue SE would be widened to the east and west within existing right-of-way to maintain existing travel lanes. The profile of the SE 8th Station on 112th Avenue SE depends on which alternative it connects with in Segment C: a retained-cut station if connecting with the tunnel alternatives or an at-grade station if connecting with at-grade and elevated alternatives.

There are two TPSSs for Alternative B2A, one under I–90 where I–90 touches Bellevue and the other at the SE 8th Station.

112th SE Elevated Alternative (B2E)
The 112th SE Elevated Alternative (B2E) (see Exhibit 2-26) is the same as Alternative B2A up to the South Bellevue Station and Park-and-Ride. After the station, Alternative B2E crosses to the west side of Bellevue Way SE until just south of the Bellevue Way SE/112th Avenue SE intersection, where the alternative crosses over to continue along the east side of 112th Avenue SE to SE 6th Street. The SE 8th Station is elevated for Alternative B2E. Most of the additional right-of-way would be required along the west side of Bellevue Way SE north of the South Bellevue Station and on the east side of 112th Avenue SE just south and north of SE 8th Street. There are two TPSSs for Alternative B2E, one under I–90 where I–90 touches Bellevue and the other at the SE 8th Station.

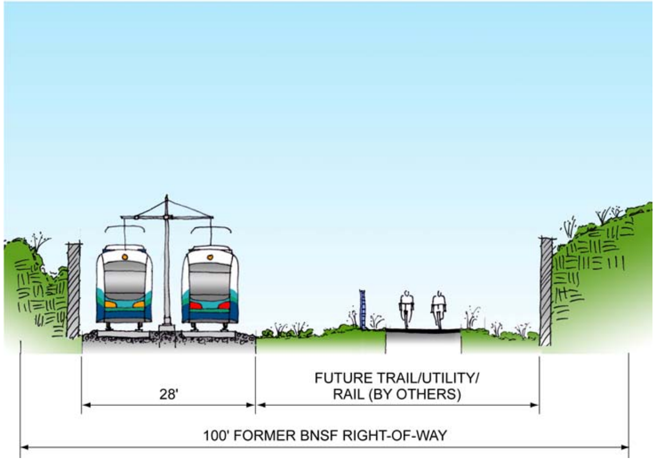
112th SE Bypass Alternative (B3)
The 112th SE Bypass Alternative (B3) (see Exhibit 2-27) follows the same route as Alternatives B2A and B2E to the South Bellevue Park-and-Ride. North of the park-and-ride, Alternative B3 mimics Alternative B2A in profile and right-of-way requirements, except that it becomes elevated along 112th Avenue SE, south of SE 8th Street, and then turns northeast in new right-of-way behind commercial buildings and up to SE 6th Street; this alternative does not include a SE 8th Station. There are two TPSSs for Alternative B3, one under I–90 where I–90 touches Bellevue and the other north of SE 8th Street.

The Alternative B3 - 114th Extension Design Option (Exhibit 2-27) is a design option to Alternative B3 that crosses the northbound lanes of 112th Avenue SE at a gated crossing north of the SE 15th Street intersection, then crosses Bellefield Office Park at-grade, transitions from at-grade to elevated structure, and extends the route at SE 8th Street farther east to 114th Avenue SE, then north along the east side of 114th Avenue SE. The extension travels through the Wilburton Park-and-Ride and then crosses 114th Avenue SE to connect to Segment C.

BNSF Alternative (B7)
The BNSF Alternative (B7) (see Exhibit 2-28) is elevated in the I–90 center roadway similar to Alternatives B2A, B2E, and B3, except that it crosses over westbound I-90 and the HOV off-ramp near Bellevue Way SE and moves to the north side of I–90. It continues eastbound elevated across Mercer Slough in a new 30-foot right-of-way until it turns north inside the former BNSF Railway corridor. As with Alternatives B2A, B2E, and B3, the eastbound I–90 HOV ramp would be closed or reconstructed and the westbound ramp would be retained with this alternative. When inside the former BNSF Railway right-of-way, Alternative B7 transitions to at-grade until the former BNSF Railway corridor turns east over I-405, at which point Alternative B7 becomes elevated, veers west, and crosses 118th Avenue SE to the 118th Station south of SE 8th Street. Automobile and pedestrian access to the 118th Station would be from 118th Avenue SE. This location is proposed as a new four-story park-and-ride structure that would replace the existing Wilburton Park-and-Ride. Alternative B7 continues northward, adjacent to the I-405 right-of-way, up to SE 6th Street. There are two TPSSs for Alternative B7, one under I–90 where I–90 touches Bellevue and the other at the 118th Station.

After the 2008 Draft EIS was published, the I-405 South Bellevue Widening Project removed the Wilburton Tunnel over I-405 and widened I-405 to the west near the Alternative B7 alignment. This widening changed the topography near the alignment for approximately 500 feet, which changed this part of the alternative from at-grade to elevated; the alternative's horizontal alignment, however, was not changed. The I-405 South Bellevue Widening Project also constructed sound walls between I-405 and some residences along 118th Avenue SE.

As described earlier, the former BNSF Railway corridor is railbanked. Exhibit 2-29 depicts a conceptual cross-section of the former BNSF Railway corridor showing an at-grade light rail route and a



28'
FUTURE TRAIL/UTILITY/ RAIL (BY OTHERS)
100' FORMER BNSF RIGHT-OF-WAY

EXHIBIT 2-29
At-Grade Track with Planned Trail in Former BNSF Railway Corridor (looking north)

future pedestrian/bicycle trail or rail use, which would be constructed by others.

Segment C: Downtown Bellevue

This segment has ten alternatives through Downtown Bellevue, crossing I-405 to connect with Segment D at NE 12th Street. The Segment C alternatives connect with most of the Segment B alternatives, although the Bellevue Way Tunnel Alternative (C1T) connects only with the Bellevue Way Alternative (B1), and the 110th NE Elevated (C8E) and the 114th NE Elevated (C14E) Alternatives connect only with Alternatives B3 (including the B3 - 114th Extension Design Option) and B7. Each alternative in this segment has two or three stations at six possible locations: Old Bellevue, 108th, Bellevue Transit Center, Hospital, Ashwood/Hospital, and East Main stations. Exhibit 2-18 shows the locations and overall features of the ten alternatives, and Exhibits 2-30 to 2-41 show details of each alternative. Additional information on the proposed stations is provided in Table 2-3.

As discussed previously, the Sound Transit Board identified two preferred alternatives in Segment C in April and July 2010: *Preferred 108th NE At-Grade Alternative (C11A)* and *Preferred 110th NE Tunnel Alternative (C9T)*. *Preferred Alternative C11A* is at-grade in Downtown Bellevue, while *Preferred Alternative C9T* is in a tunnel in Downtown Bellevue. *Preferred Alternative C9T* is preferred based on a term sheet (a preliminary agreement) executed between Sound Transit and the City of Bellevue related to finding additional funding sources and scope reductions that would decrease the affordability gap between *Preferred Alternative C11A* and this tunnel alternative. *Preferred Alternative C11A* is preferred if additional funding and scope reductions cannot be found to afford the tunnel.

EXHIBIT 2-30
Preferred 108th NE At-Grade Alternative (C11A)

In the following descriptions of alternatives, the connectors are described where applicable, then the mainline portion of the alternative is described. The descriptions of the connectors end at the common point where the mainline description continues.

Preferred 108th NE At-Grade Alternative (C11A)

Preferred Alternative C11A (see Exhibit 2-30) travels from Segment B at-grade north along 108th Avenue NE, turns east at NE 6th Street, and crosses over I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From *Preferred Alternative B2M*, *Preferred Alternative C11A* transitions from center-running on 112th Avenue SE to side-running on the west side, crossing the southbound lanes south of SE 6th Street. It continues north from SE 6th Street, remaining at-grade along the west side of 112th Ave SE, transitioning from an at-grade profile to retained fill on the west side of 112th Avenue SE, and then becomes elevated to cross SE 1st Place and turns west. *Preferred Alternative C11A* then travels on the south side of Main Street in a retained fill to the 108th Station between 108th and 110th Avenues.

- From Alternatives B3, B3 - 114th Extension Design Option, and B7, the connectors are elevated and converge to a single route just north of SE 6th Street. The connector then heads northwest, crossing over 112th Avenue SE to travel along the south side of Main Street to the 108th Station.

From the 108th Station, *Preferred Alternative C11A* turns north at-grade, crossing Main Street to the center of 108th Avenue NE. At NE 6th Street, *Preferred Alternative C11A* turns east along the center of NE 6th Street to the at-grade Bellevue Transit Center Station, located at the existing Bellevue Transit Center between 108th and 110th Avenues NE. *Preferred Alternative C11A* then crosses 110th Avenue NE at-grade and transitions to a retained fill and then to an elevated profile between 110th and 112th Avenues NE before crossing 112th Avenue NE. *Preferred Alternative C11A* transitions from center-running on NE 6th Street between 110th and 112th Avenues NE to the north side of NE 6th Street before crossing I-405 and 116th Avenue NE. *Preferred Alternative C11A* then turns north along the former BNSF Railway corridor to cross NE 8th Street and reach the elevated Hospital Station before connecting with Segment D alternatives from the former BNSF Railway corridor. The Hospital Station would not preclude the development of a pedestrian or trail connection over NE 8th Street that would be designed and constructed by others. There is only one TPSS for *Preferred Alternative C11A*, located near the intersection of Main Street and 112th Avenue SE.

Preferred 110th NE Tunnel Alternative (C9T)

Preferred Alternative C9T (see Exhibit 2-31) travels from Segment B in a tunnel north along 110th Avenue NE, turns east at NE 6th Street, and crosses over I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From *Preferred Alternative B2M*, *Preferred Alternative C9T* begins on the east side of 112th Avenue SE at SE 6th Street and then transitions to the west side of 112th Avenue SE at SE 6th Street. *Preferred Alternative C9T* then travels at-grade on the west side of 112th Avenue SE before turning west at Main Street to enter the tunnel portal on Main Street. This connector requires realigning SE 4th Street through Surrey Downs Park to connect to 112th Avenue SE farther south, forming a four-way intersection at SE 6th Street.
- From Alternatives B3, B3 - 114th Extension Design Option, and B7, the connectors are elevated and converge to a single route just north of SE 6th Street. The connector then heads northwest to the elevated East Main Station south of Main Street. The connector then crosses over 112th Avenue SE to travel along the south side of Main Street and enter the tunnel portal on Main Street.

EXHIBIT 2-31
Preferred 110th NE Tunnel Alternative (C9T)

From the tunnel portal on Main Street, *Preferred Alternative C9T* continues on the south side of Main Street before turning north under 110th Avenue NE. *Preferred Alternative C9T* includes the Bellevue Transit Center Station at NE 4th Street. From this station, *Preferred Alternative C9T* continues north to NE 6th Street, where it turns east and transitions to an elevated profile in the center of NE 6th Street, and then swings to the north side of NE 6th Street to cross 112th Avenue NE, I-405, and 116th Avenue NE. *Preferred Alternative C9T* then turns north along the former BNSF Railway corridor to cross NE 8th Street and reach the elevated Hospital Station; it then connects with Segment D alternatives from the former BNSF Railway corridor. The Hospital Station would not preclude development of a pedestrian or trail connection over NE 8th Street that would be designed and constructed by others. There is only one TPSS for *Preferred Alternative C9T*, located near the intersection of Main Street and 112th Avenue SE.

Preferred Alternative C9T also has a design option, Alternative C9T – East Main Station Design Option, which would include an at-grade station just south of the intersection of 112th Avenue SE and Main Street on the west side of 112th Avenue SE (see Exhibit 2-31). This design option would only be implemented with a connection to *Preferred Alternative B2M*. Under this configuration, the SE 8th Station on *Preferred Alternative B2M* would not be built.

Bellevue Way Tunnel Alternative (C1T)
The Bellevue Way Tunnel Alternative (C1T) (see Exhibit 2-32) continues at-grade in the median of Bellevue Way SE from Alternative B1, then transitions to a tunnel in a retained cut from approximately SE 4th Street to SE 2nd Street. C1T continues in a tunnel to the underground Old Bellevue Station between Main Street and NE 2nd Street. The alternative turns east at NE 6th Street under the Bellevue Arts Museum to an underground station at the Bellevue Transit Center. Alternative C1T exits the tunnel after 110th Avenue NE in an elevated profile in the median of NE 6th and crosses 112th Avenue NE, I-405, and 116th Avenue NE before turning north inside the former BNSF Railway corridor. The Hospital Station is elevated just north of NE 8th Street. Alternative C1T then descends to an at-grade profile to cross under NE 12th Street, where it connects to Segment D alternatives. The Hospital Station could include development of a pedestrian or trail connection over NE 8th Street that would be designed and constructed by others. There is only one TPSS for Alternative C1T, located under the elevated guideway near NE 8th Street.

106th NE Tunnel Alternative (C2T)
The 106th NE Tunnel Alternative (C2T) (see Exhibit 2-33) travels from Segment B in a tunnel under 106th Avenue NE, turns east at NE 6th Street, and crosses over I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternative B2A, Alternative C2T transitions into a retained cut, then into a tunnel in the median of 112th Avenue SE before turning northwest under the Surrey Downs Park, on the District Court House side, and travels diagonally to connect to 106th Avenue NE at Main Street.
- From Alternative B2E, elevated on the east side of 112th Avenue, the connector turns west at Main Street and descends into a tunnel west of 112th Avenue SE along the south side of Main Street, where it turns to align under 106th Avenue NE.
- From Alternatives B3 and B7, the connector converges in new right-of-way just south of Main Street to the retained-cut East Main Station. From there, the connector turns west at Main Street and

EXHIBIT 2-33
106th NE Tunnel Alternative (C2T)

descends into a tunnel under 112th Avenue SE along the south side of Main Street, where it turns under a small retail complex to align under 106th Avenue NE.

North of Main Street**,** Alternative C2T continues under 106th Avenue NE in a tunnel and turns east under NE 6th Street to the underground Bellevue Transit Center Station. From this point eastward, the Alternative C2T route is identical to Alternative C1T as it connects to Segment D alternatives. There is only one TPSS for Alternative C2T, located under the elevated guideway near NE 8th Street.

108th NE Tunnel Alternative (C3T)

The 108th NE Tunnel Alternative (C3T) (see Exhibit 2-34) travels from Segment B in a tunnel under 108th Avenue NE, turns east at NE 12th Street, and crosses I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternative B2A, Alternative C3T transitions into a retained cut, then tunnels in the median of 112th Avenue SE before turning northwest under the Surrey Downs Park/District Court House site and diagonally to where it connects to 108th Avenue NE at Main Street.
- From Alternative B2E, elevated on the east side of 112th Avenue, the connector turns west at Main Street and descends into a tunnel west of 112th Avenue SE along the south side of Main Street, where it turns in an easement under 108th Avenue NE.
- From Alternatives B3 and B7, the connectors converge into a new right-of-way west of I-405; then, south of Main Street, the connector descends into a retained-cut to East Main Station. From there, the connector turns west at Main Street and descends into a tunnel under 112th Avenue SE along the south side of Main Street, where it turns under 108th Avenue NE.

North of Main Street, Alternative C3T continues along 108th Avenue NE in a tunnel to the underground Bellevue Transit Center Station. The alternative continues north until turning east onto the north side of NE 12th Street. The exit portal is at approximately 110th Avenue NE, and then the guideway transitions to an elevated profile to cross over 112th Avenue NE and I-405 with the Ashwood/Hospital Station located just east of I-405. There is only one TPSS for Alternative C3T, located at the Ashwood/Hospital Station east of I-405 and north of NE 12th Street.

Couplet Alternative (C4A)

The Couplet Alternative (C4A) (see Exhibit 2-35) travels from Segment B at-grade with a northbound track on 110th Avenue NE and southbound track on 108th Avenue NE. It turns east at NE 12th Street and crosses I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternative B2A, the connector transitions from an at-grade to elevated profile on the east side of 112th Avenue. The connector turns west at Main Street and returns at-grade along the south side of the road, with single tracks to 110th and 108th Avenues NE.
- From Alternative B2E, elevated on the east side of 112th Avenue, the connector is the same as Alternative B2A.

EXHIBIT 2-35
Couplet Alternative (C4A)

- From Alternatives B3 and B7, the connectors converge just south of Main Street to the elevated East Main Station. From there, the connector turns west at Main Street, crosses over 112th Avenue SE, and descends to an at-grade profile along the south side of Main Street, with tracks to 110th and 108th Avenues NE.

Between Main Street and NE 12th Street, Alternative C4A is an at-grade couplet using 110th and 108th Avenues NE. The northbound track on 110th Avenue NE would remove one lane of traffic and 110th would become one-way in the southbound direction (Exhibit 2-36). The southbound track on 108th Avenue NE would remove one lane of traffic and assumes that 108th would become one way in the northbound direction. Under Alternative C4A, the light rail would run counterflow to automobile traffic on 108th and 110th Avenues NE, which would improve visibility with automobiles and provide protected movement through the intersection. Operating light rail vehicles in the opposite direction as automobile traffic would also allow two-way bus service in a joint-use lane between NE 4th and NE 8th Streets in Downtown Bellevue. The Bellevue Transit Center Station would be on 108th and 110th Avenues NE south of NE 6th Street. The couplet would combine into a double track going east north of NE 12th Street in an elevated profile to cross over 112th Avenue NE and I-405, with the Ashwood/Hospital Station located just east of I-405. There would be only one TPSS for Alternative C4A, located at the Ashwood/Hospital Station east of I-405 and north of NE 12th Street.

112th NE Elevated Alternative (C7E)

The 112th NE Elevated Alternative (C7E) (see Exhibit 2-37) travels from Segment B, elevated along 112th Avenue, turns east at NE 12th Street, and crosses I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternative B2A, an at-grade to elevated profile on the east side of 112th Avenue SE, the connector crosses Main Street.
- From Alternative B2E, elevated on the east side of 112th Avenue SE, the connector is the same as Alternative B2A.

From Alternatives B3 and B7, the connectors converge just south of Main Street to an elevated East Main Station. From there, the connector turns northwest along the east side of 112th Avenue SE and crosses Main Street.

North of Main Street, Alternative C7E is an elevated profile along the east side of 112th Avenue SE, with the Bellevue Transit Center Station south of NE 6th Street and a pedestrian overpass connecting to the Bellevue Transit Center. Alternative C7E continues elevated, turning east at NE 12th Street to cross over 112th Avenue SE and I-405, with the Ashwood/Hospital Station located just east of I-405. There is only one TPSS for Alternative C7E, located at the Ashwood/Hospital Station east of I-405 and north of NE 12th Street.

110th NE Elevated Alternative (C8E)

The 110th NE Elevated Alternative (C8E) (see Exhibit 2-38) travels from Segment B adjacent to 114th Avenue/I-405, turns west at NE 2nd Street and north elevated along 110th Avenue NE, turns east at NE 12th Street, and crosses I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternatives B3 and B7, the connectors converge just south of Main Street to the elevated East Main Station. From there, the connectors continue north over Main Street adjacent to I-405/114th Avenue.

North of Main Street, Alternative C8E is an elevated profile adjacent to 114th Avenue NE/ I-405, turning west at NE 2nd Street, crossing over 112th Avenue NE, and turning north at 110th Avenue NE to the median of the road and to an elevated Bellevue Transit Center station south of NE 6th Street. Alternative C8E continues elevated in the median of 110th Avenue NE, turning east at NE 12th Street to cross over 112th Avenue NE and I-405, with the Ashwood/Hospital Station located over I-405. There is only one TPSS for C8E, located under the elevated guideway after the I-405 crossing, north of NE 12th Street.

110th NE At-Grade Alternative (C9A)

110th NE At-Grade Alternative (C9A) (see Exhibit 2-39) travels from Segment B at-grade north along 110th Avenue NE, turns east at NE 6th Street, and crosses over I-405 to connect with the Segment D alternatives.

Connectors from Segment B:

- From Alternative B2A, Alternative C9A begins at-grade in the center of 112th Avenue SE and transitions to retained fill just north of SE 6th Street. The alternative then transitions to elevated and curves slightly to the east side of 112th Avenue SE before turning west and crossing over 112th Avenue SE and transitioning to at-grade along Main Street. This connector requires widening 112th Avenue SE to the east for

110th NE Elevated Alternative (C8E)

northbound traffic where the profile is at-grade and transitioning to elevated. Once the connector is elevated, northbound traffic travels under the elevated portions before 112th Avenue SE rejoins the original alignment.

- From Alternatives B3, B3 - 114th Extension Design Option, and B7, the connectors are elevated and converge to a single route just north of SE 6th Street. The connector then heads northwest to the elevated East Main Station south of Main Street. The connector then crosses over 112th Avenue SE to travel west along the south side of Main Street.

Alternative C9A heads west on the south side of Main Street at-grade before turning north in the center of 110th Avenue NE and traveling at-grade in the center of the street to NE 6th Street, where it turns east to a Bellevue Transit Center Station located between 110th and 112th Avenues NE. From the station, this alternative travels east in an elevated profile over 112th Avenue NE, I-405, and 116th Avenue NE. Alternative C9A then turns north along the former BNSF Railway corridor to cross NE 8th Street and reach the elevated Hospital Station, then connects with Segment D alternatives from the former BNSF Railway corridor. The Hospital Station could include development of a pedestrian or trail connection over NE 8th Street that would be designed and constructed by others. There is only one TPSS for Alternative C9A, located near the Hospital Station.

114th NE Elevated Alternative (C14E)

The 114th NE Elevated Alternative (C14E) (see Exhibit 2-40) travels from Segment B adjacent to 114th Avenue/I-405, turns east to cross I-405 between NE 6th Street and NE 8th Street, and connects with the Segment D alternatives.

Connectors from Segment B:

- From Alternatives B3, B3 - 114th Extension Design Option, and B7, the connectors are elevated and converge to a single route just north of SE 6th Street. The connector then heads north, crossing over Main Street just west of and adjacent to I-405/114th Avenue NE. This alternative does not include the East Main Station.

North of Main Street, Alternative C14E is elevated the entire distance and crosses over I-405 beginning at NE 6th Street. The Bellevue Transit Center Station is located on an elevated structure above 114th Avenue NE, between NE 4th and 6th Streets, east of the existing Bellevue Transit Center. To provide better access from the existing Bellevue Transit Center, a moving sidewalk connects the station to City Hall Plaza, located across the street from the Bellevue

114th NE Elevated Alternative (C14E)

Transit Center. Under Alternative C14E, a 200-space underground parking structure could be implemented by others as part of a larger development project on nearby property. After crossing I-405, Alternative C14E crosses 116th Avenue NE in an elevated profile and then turns north in the former BNSF Railway corridor to an elevated Hospital Station. The Hospital Station could include development of a pedestrian or trail connection over NE 8th Street that would be designed and constructed by others. There is only one TPSS for Alternative C14E, located near the Hospital Station.

Interim Termini in Segment C

The East Link Project might be constructed in phases, depending on available funding or other factors. In Segment C, an interim terminus might be located at the Hospital Station or Ashwood/Hospital Station, depending on the alternative selected. However, operational plans might require constructing a maintenance facility. The closest of the proposed maintenance facility alternative sites is in Segment D, so an access track and maintenance facility would be built beyond Segment C under this phasing scenario. In addition, an interim terminus would require storage tracks up to 850 feet beyond the station platform for temporary layover of a four-car train. The preferred location for these storage tracks would be an extension within the former BNSF Railway corridor, north of the Hospital Station.

City of Bellevue's Proposed B7-Revised (B7R)

In response to the Draft EIS and the SDEIS, the City of Bellevue developed conceptual designs for modifications to Alternative B7 connecting to *Preferred Alternative C9T* and referred to this set of modifications as B7R (see Exhibit 2-41). The City of Bellevue also commissioned a preliminary study of the B7R modifications (City of Bellevue's *B7R Interim Analysis Report* [2011] in Appendix K). While the City's study was not as detailed as the environmental work prepared by Sound Transit (and in some areas it used different methodologies), information from the study is included and discussed in Chapter 7 for purposes of comparison. The B7R is compared with the combination of Alternative B7 and *Preferred Alternative C9T* in Chapter 7.

The B7R, studied by the City of Bellevue, follows the same general route as Alternative B7 and *Preferred Alternative C9T* except the route between the East Main Station and the Bellevue Transit Center Station is different than *C9T*. B7R has a light rail station (referred to as the A2 Station) located adjacent to and north of I-90 over the I-90/Bellevue Way SE interchange, with a pedestrian walkway to a new parking garage and transit center on the west side of Bellevue Way SE in the Enatai neighborhood (Exhibit 2-41). The A2 Station replaces the 118th Station of Alternative B7, and the South Bellevue Park-and-Ride Lot is assumed to be closed. Roadway access to the A2 Station parking garage and transit center would be from Bellevue Way SE and 113th Avenue SE and would require a new overpass over Bellevue Way SE. B7R modifies the *Preferred Alternative C9T* route by crossing under Main Street north of the East Main Station and then enters a tunnel north of Main Street that turns west at NE 2nd Street and connects to the Bellevue Transit Center Station, as opposed to *Preferred Alternative C9T,* which enters a tunnel portal at the southwest corner of Main Street and 112th Avenue. B7R includes East Main and Bellevue Transit Center Stations. While not studied by the City of Bellevue, the extension north to the Hospital Station is assumed to be the same as with *Preferred Alternative C9T*.

EXHIBIT 2-41
City of Bellevue Proposed B7/C9T Revised (B7R)

Segment D: Downtown Bellevue to Overlake Transit Center

There are four alternatives in Segment D, which serve both the City of Bellevue's Bel-Red Corridor and Redmond's Overlake Village planning areas. All Segment D alternatives begin with connections from either the north side of NE 12th Street across 116th Avenue NE or from the former BNSF Railway corridor coming from NE 6th Street. These are referred to below as connections from "NE 12th" or "former BNSF." Segment D alternatives have between two and four stations at four possible locations: the 120th, 130th, Overlake Village, and Overlake Transit Center stations. *Preferred NE 16th At-Grade (D2A),* NE 16th Elevated (D2E), and NE 20th (D3) Alternatives have the option of building either the 120th Station or the 130th Station, or building both stations. Exhibit 2-19 shows the locations and overall features of the Segment D alternatives, and Exhibits 2-42 to 2-45 show details of each alternative. Additional information on the proposed stations is provided in Table 2-3. The Sound Transit Board identified the *Preferred NE 16th At-Grade Alternative (D2A)* as the preferred alternative in Segment D.

Preferred NE 16th At-Grade Alternative (D2A)

Preferred Alternative D2A (see Exhibit 2-42) travels parallel to and north of a new NE 15th Street corridor east from the former BNSF Railway corridor in a mixed at-grade, retained-cut, and elevated profile.

Preferred Alternative D2A leaves the former BNSF Railway corridor at-grade and then transitions to a retained cut under 120th Avenue NE to a retained-cut 120th Station. After leaving the 120th Station, the route continues in a retained cut under 124th Avenue NE before transitioning to an elevated profile over the West Tributary of Kelsey Creek and then returns to the at-grade 130th Station. This alternative would also construct a surface park-and-ride lot at either the 120th or the 130th Station, but not at both stations. *Preferred Alternative D2A* continues at-grade on NE 16th Street, turns north at 136th Place NE, and crosses NE 20th Street at-grade until it transitions to an elevated structure along the south side of SR 520. This alternative then continues northeast to the Overlake Village Station west of 152nd Avenue NE, next to SR 520, and transitions to a retained-cut profile after the station until reaching the retained-cut Overlake Transit Center Station, which includes a proposed four-story parking structure.

Two bicycle/pedestrian bridges connecting to the north side of SR 520 are being considered and would be funded by others at the Overlake Village and Overlake Transit Center Stations. From the Overlake Transit Center Station, the route descends into a retained-cut profile on the east side of SR 520 and crosses under NE 40th Street before connecting with all Segment E alternatives.

Any station on *Preferred Alternative D2A* might serve as an interim terminus, which would include tracks north of the station for train storage and turnback operations. However, the preferred location for these storage tracks would be in the former BNSF Railway corridor north of the Segment C/D break. If such a feature were built at an interim terminus station, then the project might also include parking for operators, and office/storage space for light maintenance activities such as cleaning interiors of vehicles.

Preferred Alternative D2A also includes two design options (as shown in Exhibit 2-42). The Alternative D2A - 120th Station Design Option follows the same horizontal alignment between 120th and 124th Avenues NE, but it is at-grade instead of in a retained cut, with an at-grade 120th Station, then transitions to elevated over 124th Avenue NE. The Alternative D2A - NE 24th Design Option leaves the SR 520 corridor at NE 24th Street and runs elevated along the north side of NE 24th Street. After crossing 148th Avenue NE, D2A - NE 24th Design Option turns north, then becomes at-grade along the west side of 152nd Avenue NE to the Overlake Village Station, then continues north to rejoin the SR 520 right-of-way. There are three TPSSs for *Preferred Alternative D2A*: one near the 120th Station, one located under the elevated guideway at NE 24th Street, and a third at the Overlake Transit Center Station.

NE 16th Elevated Alternative (D2E)

The NE 16th Elevated Alternative (D2E*)* (see Exhibit 2-43) is approximately an elevated version of *Preferred Alternative D2A* until 132nd Avenue NE, where Alternative D2E crosses to the south side of NE 16th Street, requiring street widening, then transitions to the west side of 136th Place NE, also requiring about 10 feet of street widening. Just north of NE 20th Street, D2E has a similar route to the Alternative D2A - NE 24th Design Option, except D2E remains on the south side of NE 24th Street before turning north along the west side of 152nd Avenue NE. There are two TPSSs for D2E: one located under the elevated guideway north of NE 20th Street and another at the Overlake Transit Center Station.

NE 20th Alternative (D3)

The NE 20th Alternative (D3) (see Exhibit 2-44) follows approximately the same route as *Preferred Alternative D2A* until Alternative D3 approaches NE 20th Street, where it turns east into the median of NE 20th Street at-grade, requiring widening on either side of the road, then into a retained cut east of 140th Avenue NE.

EXHIBIT 2-45
SR 520 Alternative (D5)

Alternative D3 remains in a retained-cut profile, heading north at 152nd Avenue NE, and transitions to an at-grade center-running route just south of NE 24th Street. 152nd Avenue NE would be widened to the east and west. The alternative continues north to Overlake Village and then is similar to the D2A - NE 24th Design Option profile and station descriptions, except that D3 is in the median of 152nd Avenue NE and the Overlake Village Station is closer to NE 24th Street. There are two TPSSs for Alternative D3: one located adjacent to the route at the intersection of 136th Place NE and NE 20th Street, and another at the Overlake Transit Center Station.

SR 520 Alternative (D5)

The SR 520 Alternative (D5) (see Exhibit 2-45) is elevated from the north side of NE 12th Street, or at-grade in the former BNSF Railway corridor, turns east at approximately NE 20th Street, crosses Northup Way, and continues east on the south side of SR 520. The alternative crosses over NE 24th Street and then transitions into a retained-cut profile under 148th Avenue NE and then into the retained cut/at-grade station at the Overlake Village Station behind the Safeway store or at the Overlake Village Station at NE 25th Street along the west side of 152nd Avenue NE. From 152nd Avenue NE, Alternative D5 is similar to the D2A - NE 24th Design Option, going to Segment E. There are two TPSSs for Alternative D5: one located under the elevated guideway east of 140th Avenue NE and another at the Overlake Transit Center Station.

Interim Termini in Segment D

Depending on available funding, buildout of the selected alternative in Segment D may have an interim terminus at any of the proposed stations. This would include access tracks to connect with a maintenance facility within Segment D, if one is constructed. In addition, an interim terminus would require storage tracks up to 850 feet beyond the terminus station platform for temporary layover of a four-car train.

Segment E: Overlake Transit Center to Downtown Redmond

Three alternatives are considered for Segment E. All Segment E alternatives follow one route from Segment D along the south side of SR 520 until they split into three different routes accessing Downtown Redmond. From the Overlake Transit Center, all Segment E alternatives follow the south side of SR 520 and under NE 40th Street, NE 51st Street, and NE 60th Street in a retained-cut profile. The three alternatives split into three different routes at the SR 520 interchange with West Lake Sammamish Parkway. The *Preferred Marymoor Alternative (E2)* crosses the interchange to continue east along the south side of SR 520.

Alternatives in this segment have either two or three stations at these potential locations: Redmond Town Center, SE Redmond, Downtown Redmond, and Redmond Transit Center. Exhibit 2-20 shows the locations and overall features of the Segment E alternatives, and Exhibits 2-46 to 2-48 show details of each alternative and the design option. Additional information on the proposed stations is provided in Table 2-3. The Sound Transit Board identified *Preferred Marymoor Alternative (E2)* as the preferred alternative in Segment E.

Preferred Marymoor Alternative (E2)

Preferred Marymoor Alternative (E2) (Exhibit 2-46) travels parallel to and east of SR 520 in a combination of retained-cut and at-grade profiles and transitions to an elevated profile on the south side of SR 520 on a new bridge over the Sammamish River. *Preferred Alternative E2* then descends to at-grade, straddling the SR 520 right-of-way and Marymoor Park property line to the SE Redmond Station on the south side of the SR 520 and SR 202 interchange. This station includes a park-and-ride with a structured parking garage.

After the SE Redmond Station, *Preferred Alternative E2* turns northwest, goes under the SR 520 and SR 202 interchange, and enters the former BNSF Railway corridor elevated over Bear Creek. *Preferred Alternative*

EXHIBIT 2-48
Leary Way Alternative (E4)

E2 then becomes at-grade to cross 170th Avenue NE and continue in the former BNSF Railway corridor to the Downtown Redmond Station and terminates northwest of Leary Way. An 800-foot-long tail track extends past the station for train layovers and turnbacks. This tail track includes a maintenance building and an employee parking lot with approximately 20 parking stalls.

There are two TPSSs for *Preferred Alternative E2*: one located under the elevated guideway near the West Lake Sammamish Parkway/SR 520 interchange and another along the former BNSF Railway corridor near 166th Avenue NE.

The alignment of *Preferred Alternative E2* in Downtown Redmond as shown in Appendix G1 (Conceptual Design Drawings) and the City of Redmond's *Central Connector Master Plan,* to be adopted in June 2011, are not entirely consistent primarily because of City plans for utility upgrades and the regional trail extension in the former BNSF Railway corridor and NE 76th Street rights-of-way. When funding is available to advance the design work for Segment E, Sound Transit will work with the City of Redmond to adjust the design within the BNSF and NE 76th Street right-of-way to accommodate the potential for future freight/commuter rail, local and regional utilities, the trail, and automobile traffic on NE 76th Street as well as East Link light rail. *Preferred Alternative E2* also has a design option, Alternative E2 - Redmond Transit Center Station Design Option, that has a station at Redmond Town Center, after which the route would turn north on 161st Avenue NE in the center of the roadway, with a terminus station at the Redmond Transit Center. An 800-foot-long tail track extends past the station for train layovers (see Exhibit 2-46).

Redmond Way Alternative (E1)

The Redmond Way Alternative (E1) becomes elevated and crosses north over SR 520 (see Exhibit 2-47), follows the northwest side of West Lake Sammamish Parkway, and turns northeast on the south side of Redmond Way in a new bridge structure over the Sammamish River. Alternative E1 continues along Redmond Way and turns southeast into an at-grade profile in the former BNSF Railway corridor to Redmond Town Center Station at NE 76th Street, then transitions to an elevated structure over Bear Creek and the SR 520/SR 202 interchange to the terminus, SE Redmond Station. This station includes a four-story park-and-ride facility in the industrial park adjacent to the former BNSF Railway corridor. An 800-foot-long tail track extends past the station for train layovers.

There are two TPSSs for E1: one located under the elevated guideway adjacent to West Lake Sammamish Parkway and another at the SE Redmond Station.

Leary Way Alternative (E4)

The Leary Way Alternative (E4) (see Exhibit 2-48) crosses north over SR 520 and is elevated on the northwest side of West Lake Sammamish Parkway, and then turns northeast along the south side of Leary Way, crossing the Sammamish River on a new bridge structure. The alternative then transitions to an at-grade profile south of Bear Creek Parkway and turns southeast in the former BNSF Railway corridor to the Redmond Town Center Station between 164th Avenue NE and 166th Avenue NE. The alternative continues along the former BNSF Railway corridor, crosses over Bear Creek on a bridge, and then transitions into a retained-cut profile under SR 520 before terminating in an at-grade profile at the SE Redmond Station.

The SE Redmond terminus station includes a four-story park-and-ride facility in the industrial park adjacent to the former BNSF Railway corridor. A 1,600-foot-long tail track extends past the station for train layovers. There are two TPSSs for Alternative E4: one located adjacent to the route before approaching West Lake Sammamish Parkway and another at the SE Redmond Station.

Interim Termini in Segment E

In Segment E, either the SE Redmond or the Downtown Redmond Station for *Preferred Alternative E2* or the Redmond Town Center Station for Alternatives E1 or E4 could become an interim terminus. Remaining stations in Segment E are considered to be the final terminus station for East Link.

2.3.3 Maintenance Facility Alternatives

Sound Transit's Link Operations and Maintenance Facility is located south of Downtown Seattle. A second storage and light maintenance facility would be needed with full buildout of the East Link Project. A second light rail storage and light maintenance facility was funded as part of ST2 to support systemwide expansion, with funding contributions from the King County and Snohomish County subareas. This facility's location will be determined through future operations analysis and site planning. Because the facility could be located in the East Link corridor, this Final EIS evaluates alternative sites but does not identify a preferred facility location. This facility would require approximately 10 to 15 acres of land and would primarily serve the following functions:

- Overnight and midday storage for approximately 40 to 50 vehicles
- Carwashing facility for exterior vehicle cleaning
- Interior cleaning of light rail vehicles
- Daily service and inspection of revenue vehicles
- Corrective and preventive maintenance
- Maintenance of track facilities
- Operating offices
- Light rail vehicle operator reporting and ready-room areas

With East Link service to Overlake Transit Center as an interim terminus, overnight vehicle storage would be located at the tail tracks at the end of the line and/or in the storage track in the former BNSF Railway corridor described as part of *Preferred Alternative D2A*. Vehicle maintenance and repair would remain at the existing Link Operations and Maintenance Facility in Seattle. Exhibit 2-49 illustrates a prototypical maintenance facility layout. Table 2-4 describes the characteristics of the proposed maintenance facilities.

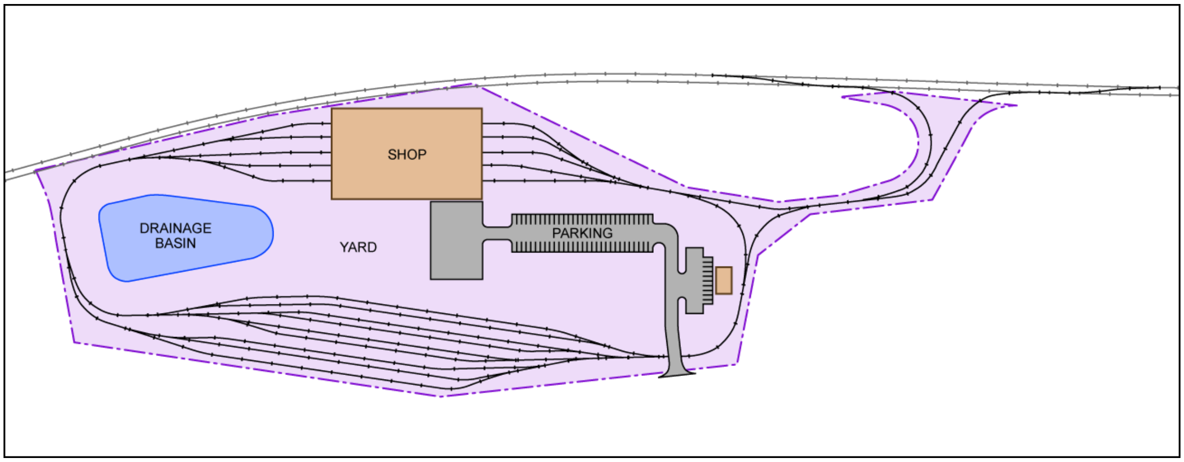

EXHIBIT 2-49
Prototypical Layout of East Link Maintenance Facility

TABLE 2-4
Maintenance Facility Characteristics

	Maintenance Facility Size (acres)	Access Track (feet)
MF1, NE 116th Maintenance Facility		
From *Preferred NE 16th At-Grade (D2A)*, NE 16th Elevated (D2E), and NE 20th (D3) Alternative	11.6	1,800
From SR 520 Alternative (D5)	11.7	1,050
MF2, BNSF Maintenance Facility		
From *Preferred NE 16th At-Grade (D2A)*, NE 16th Elevated (D2E), and NE 20th (D3) Alternative	12.3	1,600
From SR 520 Alternative (D5)	14.7	1,500
MF3, SR 520 Maintenance Facility		
From *NE 16th At-Grade (D2A)* and Elevated (D2E) Alternatives	14.2	1,100
From NE 20th Alternative (D3)	14.2	460
From SR 520 Alternative (D5)	14.2	1,300
MF5, SE Redmond Maintenance Facility		
From Redmond Way Alternative (E1)	11.5	1,300
From Marymoor Alternative (E2)	14.9	1,000
From Leary Way Alternative (E4)	14.9	800

There are four alternative maintenance facility sites, three in Segment D and one in Segment E. All the route alternatives in Segment D were designed with access to any of its three alternative maintenance facilities; likewise, all Segment E alternatives could connect to the maintenance facility MF5. Exhibits 2-19 and 2-20 show the potential maintenance facility locations in Segments D and E. Details are shown in Exhibits 2-42 to 2-45 for the Segment D sites and in Exhibits 2-46 to 2-48 for the Segment E sites. As described above, no preferred maintenance facility alternative has been identified.

116th Avenue NE Maintenance Facility (MF1). MF1 is between 116th Avenue NE and the former BNSF Railway corridor. Constructing this facility would require substantial cut and fill to create a flat area for operations.

124th Avenue NE Maintenance Facility (MF2). MF2 is between 120th Avenue NE and the former BNSF corridor and would require a minor amount of cut and fill to create a flat area.

SR 520 Maintenance Facility (MF3). MF3 is adjacent to the south side of the SR 520 right-of-way between roughly 130th Avenue NE and 135th Avenue NE.

SE Redmond Maintenance Facility (MF5). MF5 has two possible locations. For the Redmond Way Alternative (E1), the maintenance facility would be located southwest of the SR 520/SR 202 interchange and would be accessed via an access track from the former BNSF Railway corridor. This site would require a moderate amount of cut and fill to create a flat area.

For *Preferred Alternative E2* and Alternative E4, the maintenance facility would be located adjacent to the former BNSF Railway corridor south of the SR 520/SR 202 interchange. For *Preferred Alternative E2*, which does not enter the former BNSF Railway corridor in this area, an access track from the new park-and-ride facility south of SR 520 would access the maintenance facility. These sites would require minimal to no grading to create a flat area for operations.

With any interim terminus station, a storage or tail track would be built beyond the station. The preferred location is a storage track in the former BNSF Railway north of the Hospital Station. If such a feature were built at an interim terminus station, the project might also include up to 10 parking spaces for operators, and office/storage space for light maintenance activities such as cleaning interiors of vehicles.

2.3.4 Capital Equipment and Operations

2.3.4.1 Overhead Contact System

Light rail vehicles are electrically powered by an overhead contact system (commonly called an "overhead catenary system," or OCS) (Exhibit 2-50). Support poles are typically located between the two tracks for at-grade and elevated profiles, except in special circumstances such as at stations, at crossover tracks, curves, and on the I–90 bridge. The support poles are between 15 and 23 feet high, and a zone clear of vegetation is maintained within about 15 feet of the centerline of the tracks. Only on I–90, the OCS would be supported either by two poles, one on each side of the guideway, or by poles on one side. In tunnels, the OCS is attached to the tunnel ceiling. Catenary poles are located approximately 200 feet apart. Two wires (the messenger wire and the contact wire) are visible between each pole for each track, or four wires for two tracks.

EXHIBIT 2-50
Overhead Catenary System

2.3.4.2 Traction Power Substations

Electric power for the trains would be provided from the existing electrical grid through TPSSs. The TPSSs are completely enclosed small metal buildings, about 20 feet by 60 feet in size, with an additional 10 to 20 feet required around each unit (Exhibit 2-51). They can be screened from view with a wall or fence. These electric substations would be installed at about 2-mile intervals. The purpose of the TPSS is to boost the power to the OCS. Automobile access is also required for each TPSS.

The locations of the TPSS are based on power distribution needs. While the approximate locations of TPSS are shown in the alternative maps in Exhibits 2-16 through 2-20, there is some flexibility in the ultimate location of these facilities. When possible, they would be placed in the footprint of a light rail station or trackway, or adjacent to the track where remaining right-of-way is available.

2.3.4.3 Tunnel Vents

Ventilation structures provide emergency ventilation and climate control for alternatives that are in a tunnel or are lidded. They require a set of vent shafts, which are typically located at stations. The surface building enclosing the shaft would include an exhaust and intake in the roof, a fan room, and space for electrical and communications equipment. These may be integrated with the structures for vertical station access. Ventilation would also be provided at the tunnel portals by jet fans, including at the portals of existing I-90 tunnels used by light rail.

EXHIBIT 2-51
Traction Power Substation

2.3.4.4 Tail Tracks and Crossover Tracks

Tail tracks are tracks that extend past a terminus station far enough for temporary layover of one four-car train—typically 850 feet beyond the last station platform. Tail tracks also enable trains to enter terminal stations at higher speeds because they provide longer safe braking distances. These tracks would be necessary at two locations as well as the ultimate terminus station. If a tail track were built at an interim terminus station, it may also include parking for operators and office/storage space for light maintenance activities such as cleaning interiors of vehicles.

Crossover tracks connect the two parallel tracks and allow trains to pass safely from one track to the other (Exhibit 2-52). Crossovers would be provided along the line to allow for scheduled maintenance that requires removing one track from service during track maintenance, to bypass a stalled train, to turn to the opposite direction, or to operate in the event of emergencies and blockages.

2.3.4.5 Vehicles and Operations

Operation of the East Link system would be integrated with the Central Link system and any future extensions north and south of Central Link. East Link is planned to operate 20 hours per day Monday through Saturday and 18 hours per day on Sunday.

Service levels would vary during the day according to ridership demand. Table 2-5 shows the expected service schedule for weekdays based on 2030 ridership forecasts.

EXHIBIT 2-52
Crossover Tracks

TABLE 2-5
Weekday Service Periods

Service Period	Time Period	Service Level	Train Frequency (minutes)
Early morning	5:00 a.m. to 6:00 a.m.	early/late	15
Morning peak	6:00 a.m. to 8:30 a.m.	peak	7
Midday	8:30 a.m. to 3:00 p.m.	base	10
Afternoon peak	3:00 p.m. to 6:30 p.m.	peak	7
Evening	6:30 p.m. to 10:00 p.m.	base	10
Evening late night	10:00 p.m. to 1:00 a.m.	early/late	15

Weekend and holiday service levels are based on early/late service levels, as shown in the table. Conventional low-floor light rail vehicles would be used to provide level boarding for all passengers and would be easily accessible by people with disabilities. Trains would operate with up to three cars during peak and off-peak periods (see Appendix E, Operating Plan Summary), although the system is designed for, and could operate with, four-car trains.

2.3.4.6 Crossing Gates and Bells

Some at-grade crossings of existing roadways would be controlled by traffic signals and/or crossing gates as traffic volumes, track alignment, and train operating speeds dictate. Crossing gates would include gate arms, flashing lights, and warning bells to warn of oncoming trains. Warning bells are electronic and sound as the gates are lowered and raised.

2.4 Overview of Construction Approach

This section provides an overview of potential construction activities and timing. The overall period from start of construction to opening the light rail line would be about 7 years. Activities would include civil construction, systems installation, testing, and startup activities. During civil construction, site preparation, primary construction, and finish construction take place. Civil construction durations for the project would range from approximately 2 to 5 years in any given portion of the corridor. Activities would be most intense in the initial part of construction, with later years involving station and tunnel finishing, and systems installation.

The major construction activities that could cause environmental impacts are as follows:

- Demolition (buildings, pavement)
- Clearing and vegetation removal
- Fill and excavation
- Utility extensions, relocations, or disruptions
- Drainage changes
- Construction easements and staging area use
- Construction activity in or near a water body or sensitive area
- Tunneling, including spoils removal and transport
- Elevated structure construction
- Ground improvements such as stone columns
- Retaining wall construction
- Pile driving or auguring piles
- Blasting (not likely)
- Temporary partial or total road or lane closures and detour routes
- Temporary, partial, or limited access
- Building temporary vehicular and pedestrian detour routes
- Delivery of materials and equipment

The following subsections provide a brief description of the methods for each major construction component.

2.4.1 Construction Sequence and Activities

Construction of linear projects is typically divided into various segments or line sections based on similarities in configurations such as at-grade, elevated structures, tunnels, or retained-cut/fill sections. These segments or line sections may include underground stations, park-and-ride facilities, station platforms, transit centers, maintenance facilities, substation and signal control facilities, and other related improvements.

A work-specific construction plan would be developed during final design to establish the various construction phases and construction contracts, their estimated schedule and duration, and appropriate sequencing. Where possible, construction activities would be coordinated with other capital improvement projects being carried out by or permitted by the local jurisdictions to help minimize construction impacts.

Typical construction for surface, elevated, and cut-and-cover tunnel guideways and stations would occur on a 5- to 6-day work week schedule and would occur primarily between the hours of 7 a.m. and 10 p.m. In some locations (such as when street or freeway detours are involved and/or daytime construction periods need to be abbreviated to reduce impacts), additional shifts, all-week, nighttime, or 24-hour construction activities could be necessary. Tunneling contractors typically work extended periods when using large and expensive tunneling equipment such as a tunnel boring machine. A typical operating regime is two 10-hour shifts each weekday with 4 hours overnight for maintenance and repair. Bored tunneling operations could take place 24 hours per day from 5 to 7 days per week.

Surface hauling operations do not need to be on the same daily working schedule as tunneling operations as long as there is sufficient spoils storage area in the construction staging areas. Excess excavated material would be removed and hauled to a permitted disposal site. Truck hauling would require a loading area, staging space for trucks awaiting loading, and provisions to prevent tracking soil on public streets. Truck haul routes would require approval by local jurisdictions. This would allow surface hauling activities to occur in off-peak periods if necessary, to be concentrated during daytime periods to minimize potential impacts from noise on sensitive receptors such as residences, or to avoid peak traffic periods.

Following excavation and completion of structures, the next phase of construction would include track work, at-grade system facilities, and other facilities such as station platforms, park-and-ride lots, transit stations, and maintenance facilities.

2.4.2 Staging Areas and Construction Easements

Construction staging areas are needed before, during, and for a short time after construction work occurs. Staging areas would be used for construction, equipment storage, construction materials delivery and storage, demolition or spoils handling (in accordance with applicable regulations), contractor trailers, access roads, and construction crew parking. At-grade, elevated, and retained cut-and-fill line sections would have construction staging areas along the routes. Where roadway right-of-way does not already exist, generally a 50-foot to 100-foot total area (including the route right-of-way) would be needed to construct the route. Contractors would generally use the property in which the facility is being constructed and property that has been acquired for right-of-way or other properties as negotiated by the contractor. Additional property may be required for contractor employee parking. Also, construction may require using one lane or even temporarily closing the road entirely for construction purposes.

In Segment A, construction of the East Link Project would require a connection to the Central Link light rail system in the Downtown Seattle Transit Tunnel at the International District/Chinatown Station. Sound Transit would plan and coordinate construction activities related to building this connection to minimize the effect on the operation of the Central Link system and bus operations. East Link Project construction would also require long-term closures of the D2 Bridge and Roadway. Buses and other vehicles that currently use the D2 Roadway would be rerouted during the active construction period.

Because the Downtown Bellevue area is densely urbanized, Segment C staging areas have been identified in order to determine associated potential impacts. Furthermore, Alternatives C2T and C3T involve a bored tunnel, which would require approximately 4 to 6 acres immediately adjacent to each tunnel portal to support tunneling activities. In addition to the activities stated above, tunnel staging areas may include many of the following activities:

- Stockpile, load, and haul tunnel spoils
- Receive and stockpile precast tunnel liners;
- Assemble the tunnel boring machine and other boring/mining equipment
- Assemble slurry wall equipment, a shotcrete plant, or a concrete batch plant

- Collect, store, and discharge construction water and groundwater

Following construction, staging sites may be redeveloped consistent with the current zoning. Exhibits 2-53 to 2-62 show the staging locations and construction methods for each alternative in Segment C. Construction easements are temporary use of property during construction and would be required in numerous locations along the route. In undeveloped land areas, 50- to 100-foot easements would be necessary to maneuver equipment and materials along the corridor during construction. Where the project has limited acquisitions on either side, construction activities may require narrow temporary easements from adjacent properties. Following construction, easements would be restored similar to preconstruction conditions.

Where the project would partially or fully close streets, traffic would need to be rerouted via detours so construction could proceed in an efficient and timely manner while still maintaining access to existing businesses and residences. Traffic closures or detours would require approval by local jurisdictions and/or WSDOT.

2.4.3 At-Grade Light Rail Construction

Construction methods and impacts would be similar to those associated with typical road construction. Utilities may be relocated first. Shallow, near-surface excavations would be required to construct the subgrade and track and station platform slabs for at-grade segments. Within road segments or paved areas, pavement would be removed first. In areas where access is not available from existing roads, a temporary construction road would be built. During the grading phase, the contractors would install culverts or other permanent drainage structures and below-grade light rail infrastructure. Underground utility work may require temporary steel plates in the roadway and temporary lane closures. Where in-street track is proposed within existing or expanded street right-of-way, grading would likely be minimal, but extensive reconstruction of streets, sidewalks, and other existing facilities may occur.

2.4.4 Retained Cut and Retained Fill Light Rail Construction

Construction of retained cut and retained fill trackway would be similar to construction of at-grade trackway, but may be more intensive and of longer duration due to the need to construct retaining walls. Construction of retained cuts and fills may include demolition of existing structures, clearing and grading, utility relocation, construction of temporary access roads, and temporary traffic detours and lane closures. Depending on the depth of the retained cut and groundwater conditions, dewatering may be necessary during construction. Fill material for retained fill construction would be delivered to the site by truck. Retained fill structures may require ground improvement, depending on the ability of existing soils to support the increased loads. Reconstruction of streets, sidewalks, and other existing facilities may also be necessary, depending on the final alignment and profile of the retained cut or retained fill.

2.4.5 Elevated Light Rail Construction

Similar to construction of at-grade trackway, construction of elevated guideway would involve demolition, clearing, grading, relocating utilities, and preparing necessary construction access. A temporary construction road would typically be built when constructing an elevated guideway in undeveloped areas or where access is not available from existing roads (primarily in parts of Segments B and D). An elevated guideway can have vegetation under and around it, although there would be a tree-clear zone within 14 feet of the closest track centerline. Constructing an elevated guideway within existing street right-of-way may cause temporary closure of some traffic lanes and require detours.

Elevated guideways and stations for light rail, similar to structures such as highway bridges, are generally reinforced concrete, steel, or combinations of both. Construction would begin with preparation work to build foundations that may consist of shallow spread footings, deep-driven or augured piles, or drilled shafts. Once foundations are in place, concrete columns would be constructed. The elevated superstructure may be steel, cast-in-place concrete, pre-cast concrete, or segmental. If steel and/or cast-in-place concrete is used, false-work would be required to support the superstructure while the cast concrete gains enough strength during curing to support itself or while the steel beams are joined through welding or bolting. If the elevated guideway is close to or within the roadway, the false-work would require temporary lane closures and traffic detours until a sufficient portion of the elevated structure is complete. Segmental construction can be built without false-work between the columns. Some short-term, partial to full street closures may be required to accommodate segmental construction activities.

2.4.6 Below-Grade Light Rail Construction

Tunnel and underground station construction may include cut-and-cover, tunnel-boring, and/or sequential excavation mining methods. Exhibits 2-54 to 2-57 illustrate which technique is planned for each of the tunnel alternatives. In general, cut-and-cover techniques would be used for all stations, where tunnels are too short to justify boring, where tunnel depths are shallow, and where tunneling may encounter soil nails or tie-backs from adjacent underground parking garages and deep building foundations. Tunneling areas could require some form of soil stabilization ahead of tunneling operations. Potential methods include jet grouting, ground freezing, rock displacement, or a combination of these. These methods are often performed from the surface. Operations entail grout storage, grout mixing, cleanup facilities, noise suppression enclosures, and other environmental considerations.

Mining is done through two techniques: using a tunnel boring machine or sequential excavation. Mined construction begins with construction of an access portal. On hillsides, the access portal can be dug directly into the hillside (using the cut-and-cover method). In flatter areas, an access shaft must first be excavated. Once a portal or shaft is dug, the mining equipment, such as a tunnel boring machine, can begin excavating earth. The resulting excavated materials (spoils) are transported to the shaft or portal for stockpiling and/or hauling.

The type of tunnel boring machine used depends on geological conditions. Some tunnel boring machines are supported by a small supply train that brings in materials and takes out the excavated spoils. Conveyors or pipes can also be used to bring out the spoils, depending on the machine type.

Sequential excavation mining consists of the excavation of a tunnel by many smaller but defined steps. This technique can use conventional excavation equipment or a rapid excavation machine rather than a tunnel boring machine. Sequential excavation is slower and more expensive than using a boring machine.

The need for fresh air requires that a mechanical ventilation system and fans be in place during mined construction. Fans may run for 24 hours a day and could be audible at tunnel portals, stations, or access locations.

Cut-and-cover stations (like cut-and-cover tunnel segments) would be excavated from the surface and are essentially large retained cuts. Utilities must be temporarily or permanently diverted or supported across the excavation. The excavation may be decked over at the street level to allow traffic to continue once the excavation is deep enough (10 to 15 feet) to allow earthmoving equipment below. Openings in the decking or bridge are needed to allow removal of the excavated material. Cut-and-cover work also requires backfill following tunnel construction. This work requires the use of material that is imported from other sites or suitable material from the excavation.

For underground construction, it is often necessary to install dewatering facilities. Dewatering can be accomplished by a number of mechanical methods, including sumps, pumps, and dewatering wells. These systems require that water be pumped to the surface and discharged or stored or recharged into the ground. Discharge would follow the National Pollutant Discharge Elimination System (NPDES) regulations enforced by the Washington State Department of Ecology (Ecology).

2.5 Environmental Commitments

Sound Transit is committed to restoring and enhancing the environment. From the agency's inception, Sound Transit has made every effort to avoid impacts on the environment on all of its projects. Sound Transit is committed to satisfying all applicable federal, state, and local environmental regulations and to mitigate significant adverse environmental project impacts responsibly and reasonably, consistent with Sound Transit policies and applicable regulations. In addition to meeting environmental commitments, Sound Transit would continue to avoid and minimize impacts where possible.

Adjustments have been made during conceptual design to avoid or minimize impacts. Following the identification of alternatives for study in this EIS, continual community outreach, workshops, and detailed studies were conducted to receive input from community members and stakeholders and hear their concerns about the alternatives, so that designs might be made sensitive to community facilities. In addition, as environmental impact information was developed, it informed the decision-making on the alternative designs. Minimization and avoidance measures have been considered for all elements of the environment in the EIS. Sometimes it is impossible to completely avoid environmental impacts. Where adverse impacts could not be avoided at this stage of design, the environmental analysis includes potential mitigation measures to reduce the overall impacts (see Chapter 3, Transportation Environment and Consequences, and Chapter 4, Affected Environment and Environmental Consequences).

This Final EIS identifies many potential measures to mitigate the adverse impacts of the project alternatives. Sound Transit has committed to some measures as part of the project; other potential measures are noted that might reduce or eliminate impacts. Mitigation measures will be refined through final design and permitting. The Record of Decision (ROD) for East Link will be issued after the Final EIS and will include a list of committed mitigation measures for the project to be built. Appendix I contains a preliminary description of mitigation commitments for the Preferred Alternative. Once an alternative is selected to be built, mitigation commitments will be finalized and documented in the NEPA Record of Decision.

In 2004, Sound Transit launched an environmental sustainability program to integrate sustainable business practices throughout the agency. The program called for annually setting and meeting measurable targets for fuel consumption, vehicle emissions, ecosystem protection, "green" procurement, recycling and waste prevention, energy and water conservation, sustainable design and building, and education and awareness programs, among others. The East Link Project selected to be built will be refined during final design. Throughout final design, Sound Transit will continue to incorporate sustainable design measures into the East Link Project.

2.6 Estimated Project Costs and Funding

The current level of project design includes uncertainties regarding the project scope, engineering data, mitigation requirements, schedule, and project delivery methods. Therefore, the project cost estimates at this stage are conceptual costs. These estimates focus on the project elements that are defined consistently across alternatives, that capture the essential physical features of alternatives, and that help distinguish alternatives from one another. The project cost estimates include the following cost elements:

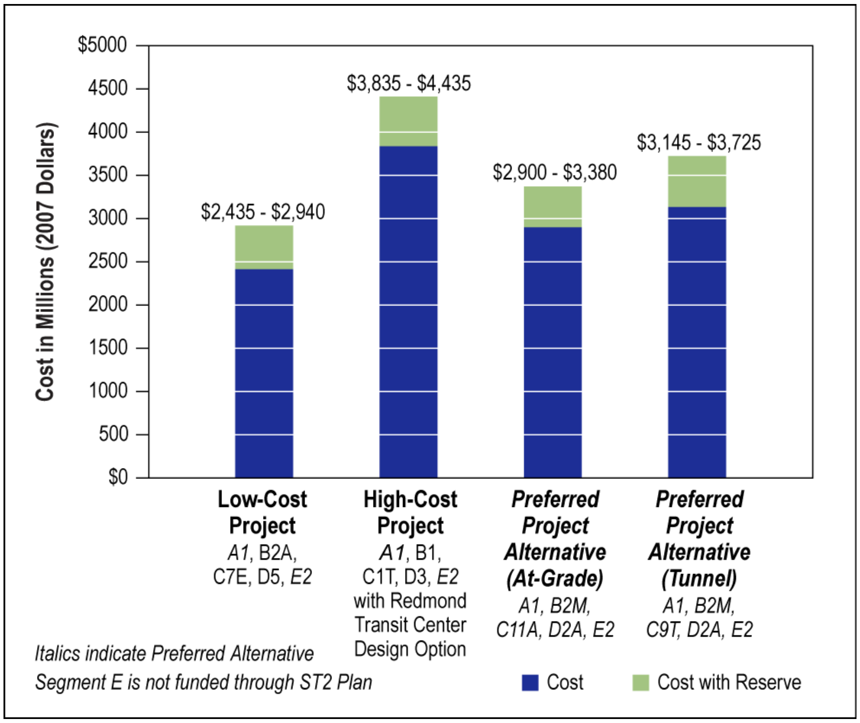

EXHIBIT 2-63
Overall Project Cost Range

- Construction costs for facilities, including the trackway/guideway, stations, maintenance facilities and associated improvements, and anticipated mitigation requirements
- Contingencies that address the varying levels of uncertainty and construction risk that have been identified for alternatives
- Right-of-way acquisition costs, including tunnel and temporary construction easements
- Costs for design, permitting, agency administration, and program management

In addition, costs for construction change orders, unallocated contingency, and project reserve were estimated as a percentage of the above estimates. Project reserve is an additional contingency intended to cover unforeseen cost impacts. The assignment and allocation of project reserve requires approval by a two-thirds (super) majority of the Sound Transit Board. Sound Transit has updated revenue forecasts to reflect the effects of the recession. The 2010 revenue forecasts lower available funds over the life of the ST2 period by an estimated 25 percent. Consequently, Sound Transit is now managing projects to the base cost estimates without project reserve. The comparative costs presented in this Final EIS reflect a range, with the low end being the base cost estimates and the high end including a project reserve. The range reflects the risk that final project costs could still exceed the base project estimate.

The East Link Project would be a composite of one alternative from each segment. Exhibit 2-63 shows a comparison of project cost for the composite of alternatives from Segment A through Segment E. It illustrates the lowest possible cost combination, the highest possible cost combination, and then the two variations in the Preferred Alternatives—with and without a tunnel in Segment C, Downtown Bellevue. The high cost includes a tunnel alternative in Segment C, and the low cost includes an elevated alternative in Downtown Bellevue.

If the project were only built to the Hospital or Ashwood/Hospital Station (east end of Segment C), the preferred alternative tunnel would be approximately $1.9 billion or $2.3 billion with reserve, and the preferred alternative at-grade would be $1.7 to just under $2 billion with reserve. In comparison, the high-cost shortened project would be approximately $2.4 to $2.8 billion with reserve, whereas the low-cost shortened project would be approximately $1.5 to $1.8 billion with reserve.

Ending at the Overlake Transit Center—the easternmost station of Segment D—the high-cost project would increase to $3.1 to $3.6 billion with reserve, whereas the preferred tunnel project would be $2.6 billion or $3.1 billion with reserve. The preferred at-grade project would be approximately $2.3 to $2.7 billion with reserve compared to the low-cost project of about $1.9 to $2.4 billion with reserve to the Overlake Transit Center. While the biggest difference is whether or not Segment C includes a tunnel, other factors influence the cost range, such as whether both the 120th and the 130th stations are built and whether portions of the route are primarily at-grade or elevated. The cost estimates by segment are presented in Section 2.6.2 after the funding discussion in Section 2.6.1.

2.6.1 Funding

Sound Transit's regional transit programs are typically funded through a combination of voter-approved tax initiatives, FTA grants, issuing bonds, and fare box revenue. Sound Transit projects are in large part funded through taxes collected in a three-county district. In November 2008, voters approved a proposition known as the Mass Transit Expansion proposal, authorizing Sound Transit to impose an additional five-tenths of one percent sales and use tax and use existing taxes to fund the local share of ST2. The East Link Light Rail Transit Project is included in ST2, which was adopted by the Sound Transit Board on July 24, 2008. The ST2 funds construction and operation of the portion of the East Link Project from Seattle to the Overlake Transit Center Station (Segments A through D).

ST2 provides funding for an at-grade or elevated alternative through Downtown Bellevue (Segment C). If the Sound Transit Board selects a tunnel alternative in this segment, additional funding sources would be required. ST2 includes environmental review but not construction for Segment E from the Overlake Transit Center Station to downtown Redmond.

The Sound Transit District has five designated subareas: Snohomish County, North King County, South King County, East King County, and Pierce County. According to current Sound Transit policy, revenues from taxes collected in each of the five subareas must generally be spent for projects and services that benefit the local subarea providing the funding. The project would use revenues from the North King County and East King County subareas. The Rainier Station would be funded from revenues from North King County, and funding for the majority of the project would come from the East King County Subarea.

2.6.2 Project Cost Estimates

The following subsections describe the range of cost estimates by segment to help compare alternatives that serve similar ridership markets.

2.6.2.1 Segment A

Preferred Alternative A1 is located exclusively within WSDOT and City of Seattle rights-of-way. The range for *Preferred Alternative A1* falls between $635 million without project reserve to up to $750 million (Exhibit 2-64) with project reserve and joint bus-rail operations between Downtown Seattle and Rainier Avenue. The I–90 Two-Way Transit and HOV Operations Project is not part of East Link and is funded separately. The cost for the project to use the I-90 center roadway is addressed in a term sheet between WSDOT and Sound Transit. Sound Transit will receive credit toward a center roadway lease for its funding contributions to the I-90 Two-Way Transit and HOV Operations Project. While the lease amount is not yet finalized, the term sheet anticipates that Sound Transit's funding of the HOV project will fully offset the cost of the I-90 Center Roadway lease.

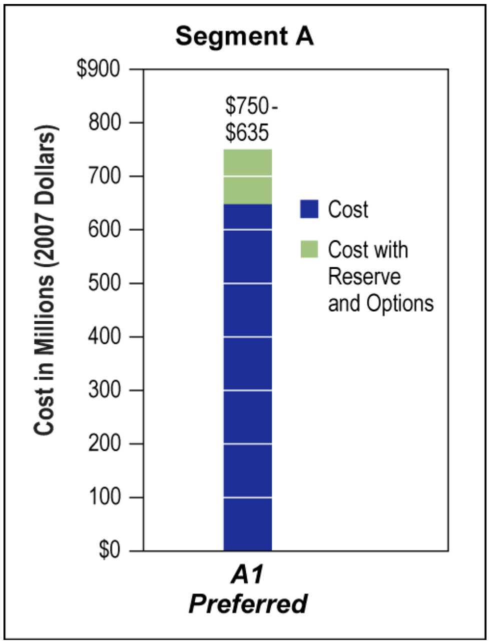

EXHIBIT 2-64
Segment A Cost Estimate

The preferred alternative that includes joint light rail and bus operation on the D2 Roadway would cost $16 million to $18 million more than the exclusive operation design option. The only other design option consideration for *Preferred Alternative A1* is a possible pedestrian bridge to the Mercer Island Station instead of access off 77th Avenue SE. The pedestrian bridge option would require approximately $6 million more than the preferred station option with access from 77th Avenue SE.

2.6.2.2 Segment B

The cost of the Segment B alternatives ranges from approximately $355 million to $590 million with reserve (Exhibit 2-65). The Bellevue Way Alternative (B1) is the lowest cost, primarily because it is completely at-grade. However, to accommodate WSDOT's requirement to maintain both HOV ramps at the I-90/Bellevue way interchange, Alternative B1 would need design revisions that would add approximately $63 million. The next lowest cost alternative is 112th SE At-Grade (B2A) followed by *Preferred 112th SE Modified Alternative (B2M)*. The *Preferred Alternative* cost range is between $470 million without reserve to $550 million with project reserve. *Preferred Alternative B2M* would result in lower costs in Segment C connecting to *Preferred Alternatives C11A* or *C9T* than the 112th SE Bypass (B3) or BNSF (B7) Alternatives because the route continues north along 112th Avenue SE at-grade while B3 and B7 are elevated and longer as they continue into downtown.

The difference in cost of *Preferred Alternative B2M* as compared with the less expensive Alternative B2A is primarily due to lidded retained cut in front of the Winters House. Alternative B7 is the most expensive of any Segment B alternative and ranges from $515 to $590 million with and without a project reserve (Exhibit 2-65). Alternative B7 is longer than the other alternatives, includes a new bridge over the Mercer Slough, and constructs a new park-and-ride rather than expanding the existing South Bellevue Park-and-Ride. The former BNSF Railway corridor also accommodates possible future freight rail or a pedestrian and bicycle trail to be built and funded by others. B3 - 114th Extension Design Option adds approximately $70 to 80 million to Alternative B3, making it comparable to BNSF Alternative (B7). The primary reasons for this high cost are both these alternatives are longer than the others and they are primarily elevated.

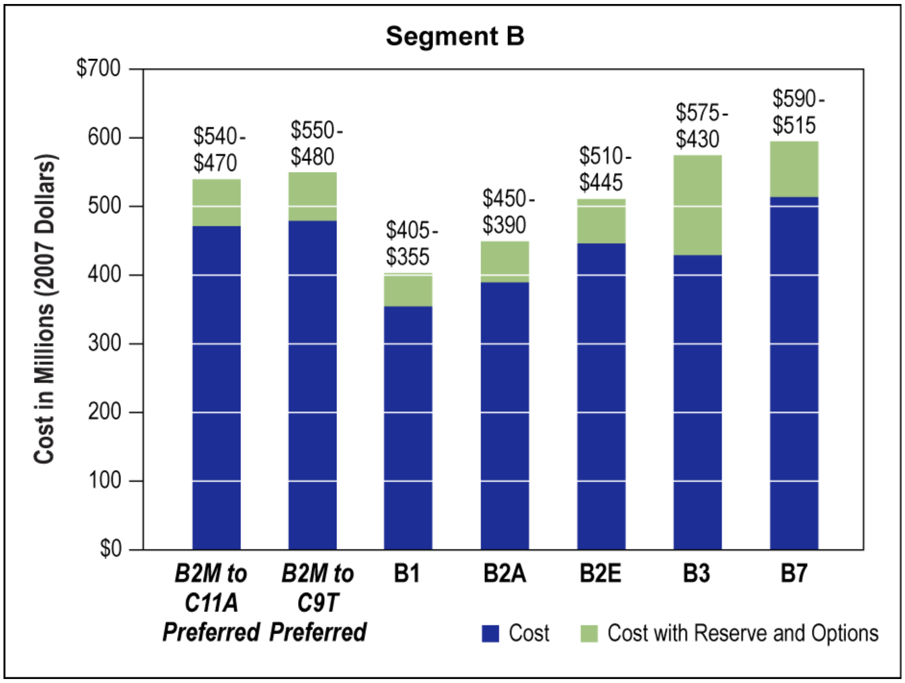

EXHIBIT 2-65
Segment B Cost Estimate

Finally, to accommodate WSDOT's requirement to maintain the east-to-northbound HOV ramp from I-90 to Bellevue Way, the non-preferred Segment B alternatives that use Bellevue Way (Alternatives B2A, B2E, and B3) would cost an additional $23 million to reconfigure the ramp. This is not reflected in the costs as discussed above.

2.6.2.3 Segment C

Segment C alternatives range from $435 million without project reserve to $1,615 million with project reserve. Segment C alternative cost estimates have the greatest cost range among the alternatives due to the inclusion of at-grade, elevated, and tunnel profiles (Exhibit 2-66). The most costly profile is a tunnel. The at-grade and elevated alternatives have similar costs in this segment due to the amount of utility relocation for at-grade profile in Segment C. The lowest cost alternative is 112th NE Elevated Alternative (C7E) because it is the shortest route and is primarily elevated.

The cost range also includes the impacts of Segment B connections. *Preferred 108th NE At-Grade (C11A)* or *Preferred 110th NE Tunnel (C9T) Alternatives* would be the lowest cost connection to *Preferred Alternative B2M.* For *C11A,* the B3 and B7 connectors are approximately $50 million more than the *B2M* connector, whereas the difference is approximately $100 million for *C9T*. The Bellevue Way Tunnel Alternative (C1T) has only one connection from Segment B—Alternative B1—and therefore has no range in project costs (other than project reserve) and remains the highest-cost Segment C alternative. The 110th NE Elevated (C8E) and 114th NE Elevated (C14E) Alternatives connect only to Alternatives B3 and B7.

Preferred Alternative C9T from *B2M,* which is estimated to range between $790 million without project reserve and $910 million with project reserve, is still substantially less than the cost of the other tunnel alternatives that range from $970 to $1,615 million. *Preferred Alternative C11A* is $555 million without project reserve and $635 million with project reserve. While the 112th NE Elevated (C7E) and the 114th NE Elevated (C14E) Alternatives are elevated, they are shorter and have lower property acquisition and utility relocation costs and therefore still result in a lower overall cost estimate than *Preferred Alternative C11A*. The 110th NE At-Grade Alternative (C9A) is comparable to *C11A*, but shorter in length and avoids rebuilding the Bellevue Transit Center and therefore costs less by approximately $100 million with and $90 million without project reserve. In addition, there are two options for the Ashwood/Hospital Station, either over I-405 for Alternative C8E or east of I-405 for Alternative C3T, C4A, or C7E. The less expensive of the two options is the station east of I-405 because of either less property acquisition or lower construction difficulty. The station located over I-405 includes an

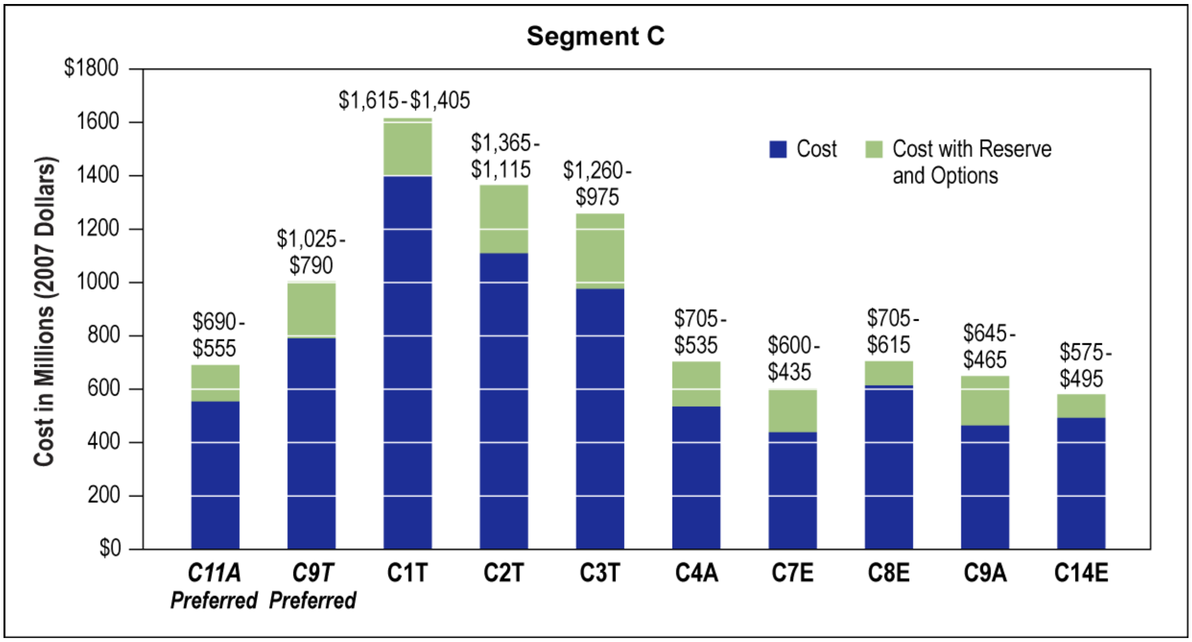

EXHIBIT 2-66
Segment C Cost Estimate

additional 25 percent cost ($12 million) for construction over I-405.

As shown in Table 2-6, the total cost of combining Segment B with Segment C alternatives provides another cost comparison. The combined cost in Table 2-6 of Segment B alternatives with Segment C alternatives reflects only the low and high cost with project reserve relative to that unique combination, whereas the low and the high costs presented in the preceding bar graphs reflect the cost range for each alternative with any of the possible combinations. Some of the cost savings in Segment B are lost when connecting to Segment C. For instance, Alternative B1 is the least expensive in Segment B, but when combined with C1T, they collectively become the most expensive combination. For *Preferred Alternative C9T,* the cost difference connecting to *B2M* is $45 to $140 million less than connecting to B3 or B7, respectively, whereas for *Preferred Alternative C11A*, connecting from B2M and B3 are similar but connecting from B7 would be $90 million more. Generally, the Segment C alternatives cost less when connecting from the alternatives that travel up 112th Avenue SE because they are shorter and on average, the connection from B7 is $100 million more than connections from 112th Avenue NE connectors. The exception is the B2A connector for both the 106th NE Tunnel (C2T) and 108th NE Tunnel (C3T) alternatives. The B2A connection through the King County District Court House site is the most costly (between $85 and $140 million more than the least costly connector because it extends these tunnels further south).

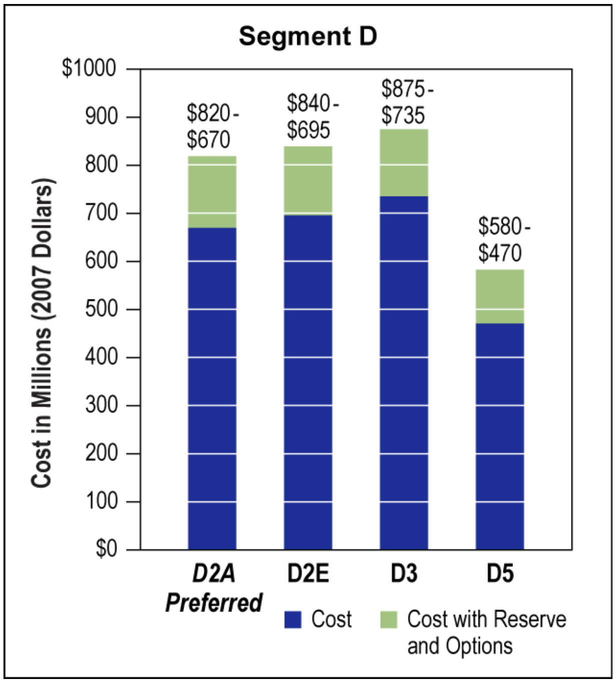

EXHIBIT 2-67
Segment D Cost Estimate

Although some of the Segment B to C alternative combinations presented in Table 2-6 are not directly studied in the EIS, they are possible, and therefore, costs are provided to complete the comparison.

2.6.2.4 Segment D

The Segment D alternatives range from approximately $470 million without project reserve to $875 million with reserve (Exhibit 2-67).

TABLE 2-6
Total Costs of Combining Segment B and C Alternatives [a] ($ millions 2007 dollars)

Alternative	***Preferred 112th SE Modified Alternative (B2M)***	**Bellevue Way Alternative (B1)**	**112th SE At-Grade Alternative (B2A)**	**112th SE Elevated Alternative (B2E)**	**112th SE Bypass Alternative (B3)**	**BNSF Alternative (B7)**
Preferred 108th NE At-Grade Alternative (C11A)	$1,020 to $1,170	NA [b]	$940 to 1,080[c]	$995 to $1,145[c]	$1,020 to $1,260	$1,110 to $1,280
Preferred 110th NE Tunnel Alternative (C9T)	$1,270 to $1,460	N/A [b]	$1,180 to 1,355[c]	1,235 to 1,420[c]	$1,315 to $1,595	$1,405 to $1,615
Bellevue Way Tunnel Alternative (C1T)	N/A[b]	$1,760 to $2,020	N/A[b]	N/A[b]	N/A[b]	N/A[b]
106th Tunnel Alternative (C2T)	N/A[b]	N/A[b]	$1,575 to $1,810	$1,565 to $1,795	$1,540 to $1,770	$1,640 to $1,885
108th Tunnel Alternative (C3T)	N/A[b]	N/A[b]	$1,480 to $1,705	$1,415 to $1,630	$1,450 to $1,670	$1,560 to $1,795
Couplet Alternative (C4A)	N/A[b]	N/A[b]	$935 to $1,075	$975 to $1,120	$1,035 to $1,195	$1,125 to $1,295
112th NE Elevated Alternative (C7E)	N/A[b]	N/A[b]	$850 to $975	$880 to $1,010	$945 to $1,085	$1,035 to $1,190
110th NE Elevated Alternative (C8E)	N/A[b]	N/A[b]	N/A[b]	N/A[b]	$1,040 to $1,195	$1,125 to $1,295
110th NE At-Grade Alternative (C9A)	N/A[b]	N/A[b]	$850 to $980[c]	$905 to $1,045[b]	$985 to $1,135	$1,070 to 1,230
114th Avenue NE Elevated Alternative (C14E)	N/A[b]	N/A[b]	N/A[b]	N/A[b]	$925 to $1,145	$1,015 to $1,165

[a] Range reflects both project cost reserves and options unique to each combination of alternatives.

[b] These Segment B-C alternative combinations are not possible.

[c] Although these Segment B-C alternative combinations are not directly studied in the EIS, they are possible, and therefore, costs are provided.

The design options for *Preferred NE 16th At-Grade Alternative (D2A)* fall within the same range— $670 million without reserve to $765 million with project reserve. *Preferred Alternative D2A* is less expensive overall than the Alternative D2A - NE 24th Design Option because remaining along SR 520 and positioning the Overlake Village Station adjacent to SR 520 as opposed to traveling along the north side of NE 24th Street and the west side of 152nd Avenue NE results in a savings of up to $50 million (or close to a 10 percent savings). The savings is a result of fewer real estate acquisitions and shorter linear miles of light rail track compared to traveling on NE 24th Street and 152nd Avenue NE. There is relatively little difference in cost among Segment D alternatives, with one exception. The SR 520 Alternative (D5) is the lowest because it avoids the construction of two stations, the 120th and 130th stations. *Preferred Alternative D2A* is somewhat lower in cost than the remaining alternatives because an at-grade profile can be less expensive than elevated and retained-cut profiles.

For the connection options to Segment C, property acquisition is the primary factor in the cost difference between the NE 12th Street connector (from C3T, C4A, C7E, or C8E) versus the former BNSF Railway connector (from *C11A, C9T*, C1T, C2T, C9A, or C14E). The former BNSF Railway connector would cost up to 7 percent more than the NE 12th Street connector for all Segment D alternatives except for Alternative D5, for which the BNSF connector would be as much as 5 percent less than the NE 12th Street connector. Alternative D5 also has two design options on the east end of Segment D, which account for less than a $3 million difference in the estimate.

For the alternatives following NE 15/16th Street Corridor, either the 120th or 130th Station may be built, or both. For *Preferred Alternative D2A* or Alternative D3, a single station rather than both stations would reduce the overall project costs by almost $11 million. For the NE 16th Elevated Alternative (D2E), the cost reduction would be approximately $47 million because an elevated station is more costly.

2.6.2.5 Segment E

Exhibit 2-68 shows the costs range in Segment E and highlights the *Preferred Marymoor Alternative (E2)* cost estimate. Segment E alternatives range from $505 million without project reserve to $795 million with project reserve. The Segment E alternatives have many portions of their routes in common. The differences lie in how they serve Downtown Redmond. *Preferred Alternative E2* costs among the lowest of the Segment E alternatives at a projected $555 million without reserve to $635 million with project reserve. Adding the Redmond Transit Center Design Option onto Alternative E2 would increase this cost by approximately $150 million. E2 - Redmond Transit Center Station Design Option is the most expensive alternative because it has the longest route with an additional station and is the only alternative with right-of-way costs along 161st Avenue NE. However, when considering *Preferred Alternative E2* (without E2 - Redmond Transit Center Design Option), then *Preferred Alternative E2* and Alternative E4 are both somewhat equal in being the lowest cost alternatives.

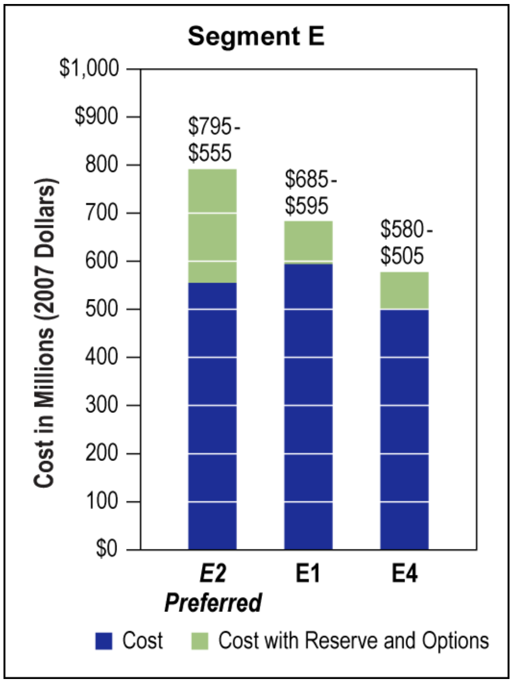

EXHIBIT 2-68
Segment E Cost Estimate

One important design consideration is where all alternatives cross the SR 520/SR 202 interchange and Bear Creek. The Redmond Way Alternative (E1) is elevated over both Bear Creek and the SR 520/SR 202 interchange. This option is approximately $11 million more than passing under the SR 520/SR 202 interchange in a retained cut and then crossing over Bear Creek, as the other two alternatives do. The range in Segment E costs is shown in Exhibit 2-68.

2.6.2.6 Maintenance Facilities

The range in maintenance facility costs is shown in Exhibit 2-69. The 116th Maintenance Facility (MF1) would be the most expensive alternative due to the amount of excavation required to create a level site, ranging from approximately $430 million without project reserve to $465 million with reserve. The variation of cost for the maintenance facility is influenced by the alternative connections. Simply stated, the longer the access track from the alternative to the maintenance facility, the higher the associated costs.

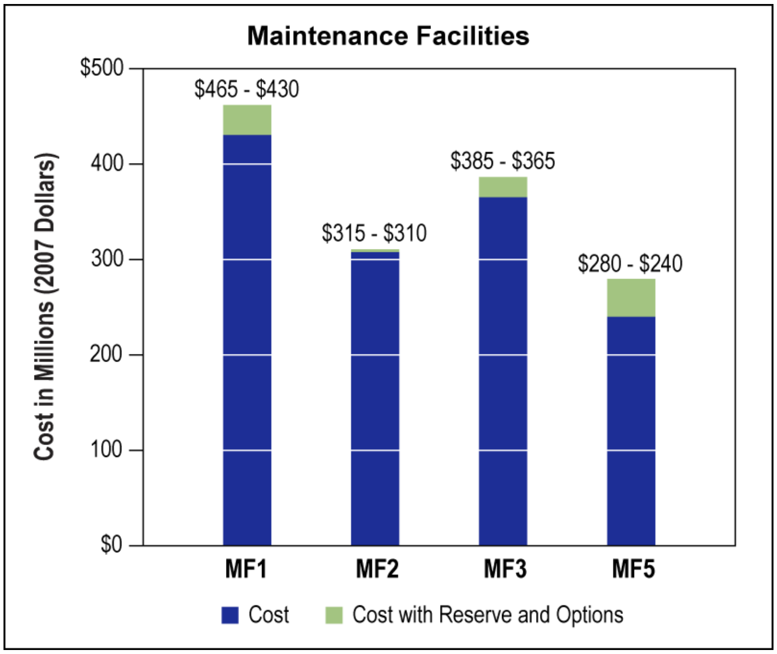

EXHIBIT 2-69
Maintenance Facilities Cost Estimate

The BNSF Maintenance Facility (MF2), at approximately $310 million to $315 million with project reserve, and the SE Redmond Maintenance Facility (MF5), between $240 million without project reserve and $280 million with reserve, would be the lowest cost alternatives due to lower site development costs, with MF5 the least expensive due to slightly lower right-of-way costs.

The SR 520 Maintenance Facility (MF3) would have higher site development costs than either MF2 or MF5, but lower costs than MF1. MF1 and MF3 would be the least expensive for Alternative D5 connection, whereas MF2 would be slightly less expensive for all other

Segment D alternatives. MF5 would have the lowest cost with connection from Alternative E1.

2.6.2.7 Operating and Maintenance Costs

Operating and maintenance costs for the East Link Project were estimated based on the estimates developed for the ST2 adopted in July 2008. East Link operating costs are the annual system operating costs for the completed light rail system in the ST2 as allocated to the East Link extension from Seattle. The light rail system operating costs are based on a labor build-up model of a type used for FTA New Starts cost estimates; it was calibrated to the relatively well-established operating and maintenance costs for the Link Initial Segment under the existing agreements with King County.

The major determinants of operating costs are service levels, running time, and trackway profile. The more frequent the service and the longer the line, the more vehicles it takes to maintain equivalent headways. Shorter alternatives with fewer stations have lower operating costs. In terms of line and station maintenance, at-grade is the lowest cost, elevated the next highest, and tunnels the highest.

The ST2 estimated annual operating cost for the East Link alternatives from Seattle to the Overlake Transit Center Station is $25 million (2007$) for 2030 (ST2, Appendix C). An additional $6 million annual operating cost is estimated for Segment E, for a total estimated annual operating cost for the entire East Link Project of about $31 million. These estimates will be refined as the project definition evolves and detailed operating plans are developed.

2.7 Next Steps and Schedule

2.7.1 Project Decision

After the Final EIS has been issued, the Sound Transit Board will make a final decision on the project alternative to be built, amending or confirming the *Preferred Alternative* identified in the this Final EIS. In addition, a second light rail storage and light maintenance facility was funded as part of ST2 to support systemwide expansion, including East Link. The location of this facility will be determined through operations analysis and future site planning which will consider locations throughout the Sound Transit service area. This future analysis would also include additional environmental review of the potential maintenance facility whether located at one of the sites evaluated in the East Link EIS or in another part of the service area.

2.7.2 Federal Approval

FTA will issue a decision document referred to as the federal Record of Design (ROD). The ROD states FTA's decision on the project, identifies the alternatives considered by FTA in reaching its decision, and itemizes Sound Transit's commitments to mitigate project impacts. Issuance of the ROD completes the NEPA process and is a prerequisite for federal funding or approvals.

2.7.3 Project Schedule

Table 2-7 shows the anticipated schedule milestones for the East Link Project. The length of time for the project would depend on available funds and construction costs. The East Link Project is included in the ST2. The ST2 funds construction and operation of the portion of the East Link Project from Seattle to the Overlake Transit Center.

Sound Transit anticipates beginning construction on the East Link Project in 2015, and construction from Seattle to Overlake would be completed in approximately 6 years, followed by approximately 1 year of startup and testing activities. Sound Transit anticipates that service would be provided to Overlake by 2022 or 2023.

2.7.4 Benefits and Disadvantages of Delaying Project Implementation

As required by SEPA (Washington Administrative Code 197-11-440(5)(c)), this section discusses the

TABLE 2-7
Project Milestones

Preliminary Design and Environmental Review	
Draft EIS published	December 2008
Draft EIS comment period	75 days
Sound Transit Board identifies preferred alternative	Spring 2009/ Spring 2010/ Summer 2010
SDEIS published	Fall 2010
SDEIS comment period	60 days
Final EIS published	Summer 2011
Sound Transit Board selects project to be built	Summer 2011
Federal Record of Decision	Fall 2011
Final Design, Construction, and Operation — ST2 Targets	
Final Design	2012 - 2015
Construction: Seattle to Overlake	2015 - 2022
Start of Service: Seattle to Overlake	2022 - 2023

benefits and disadvantages of reserving for some future time the implementation of the proposed project, as compared with possible approval at this time. The primary benefit to delaying the project would be to postpone impacts associated with project construction. Also, during project delays, planned transit-oriented development along the project corridor may be further developed to benefit transit ridership.

There are several disadvantages of delaying implementation of all or part of the project. The primary disadvantage of delaying the project would be the inability to realize a major component of the region's long-range plans for managing growth and transportation, and the benefits that result from those plans, such as increased mobility, more compact development, and a reduction in greenhouse gas emissions. PSRC and Sound Transit have studied many times the increasing congestion in the cross-lake corridor and determined that light rail to the Eastside is needed. In anticipation, local jurisdictions are meeting land use density objectives established in *Transportation 2040* (PSRC, 2010), which established long-range growth management, economic, and transportation strategies. Bellevue and Redmond have adopted transit-oriented development plans in the Bel-Red and Overlake corridor in anticipation of East Link. They have conducted feasibility studies that indicate the market forces that support dense, mixed-use development. Delays to East Link could change development patterns, leading to less dense development and lost opportunity. A substantial delay in implementing East Link would inhibit the ability of the region to accommodate growth as planned.

Implementing the East Link Project would increase person capacity on I–90 and reduce travel time during peak hours, particularly in the reverse peak direction. This would provide a benefit not only to the overall performance and mobility of I-90 but also to the key urban centers of Seattle, Bellevue, Overlake, and Redmond. If this project is delayed, this benefit would not be realized nor would the associated benefits of improved freight movement, reduced pollutants affecting air quality and global climate change, and the overall reduction of energy consumption by travelers between Seattle and Redmond. Delays would limit economic development as influenced by the movement of people and goods and the lost opportunity of linking neighborhoods and the primary Puget Sound regional employment centers. Also, developments in the project vicinity could preclude elements of the project or make it more difficult, and costly.

The potential funding implications associated with delaying the project could result in delays in project construction, which could result in higher construction costs due to inflation in future years. Delays would be likely to increase overall project and right-of-way costs. If an interim terminus is built but the rest of the project is delayed, impacts at the terminus station could increase, and costs for the overall project could increase. However, delaying all portions of the project until the entire project could be funded would delay the transportation improvements and other benefits that would be provided by that first interim segment.

Chapter 3

Transportation Environment and Consequences

3.1 Introduction

This chapter summarizes the characteristics of the transportation system in the East Link Project study area and discusses potential impacts and mitigation associated with the project alternatives described in Chapter 2. This chapter first describes the existing transportation environment, and then presents the analysis and results showing potential impacts and mitigation. A more detailed discussion of the transportation analysis and results is provided in the *Transportation Technical Report*, located in Appendix H1 of this Final Environmental Impact Statement (EIS).

3.1.1 Transportation Elements and Study Area

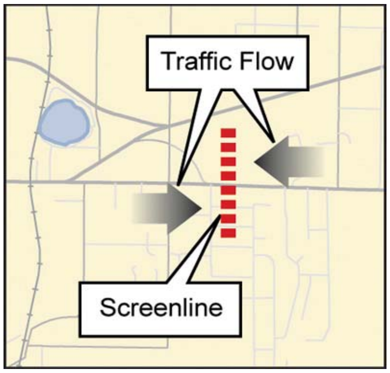
The analysis of the transportation system considered the following transportation elements:

- Regional facilities and travel patterns
- Transit operations
- Highway operations and safety
- Arterial and local street operations, safety, and parking
- Nonmotorized facilities
- Freight mobility and access
- Navigable waterways

This chapter is organized with a section on each transportation element. Each section discusses its methodology, affected environment, environmental impacts, and potential mitigation. For each of these elements, the affected environment is described under current conditions (2007), and the environmental impacts are described for the two future years, 2020 and 2030. The year 2020 was selected for analysis because it aligns with the project's estimated year of opening. The year 2030 provides a horizon-year analysis consistent with the planning period of regional and local agencies. The impact analysis compares the No Build Alternative with the East Link (light rail) alternatives.

The study area for this transportation analysis consists of the Interstate 90 (I-90) corridor between Seattle and Interstate 405 (I-405), South Bellevue, Downtown Bellevue, the Bel-Red area of Bellevue and Redmond, State Route (SR) 520 between Overlake and Downtown Redmond, and Downtown Redmond.

Exhibits 3-1 through 3-3 identify the transportation and local street analysis study area. Within the study area, approximately 151 intersections were analyzed. Pedestrian circulation was evaluated within a one-half mile radius surrounding stations, and sidewalks and on-street parking within a one-quarter-mile radius. Bicycle circulation was evaluated within a one-mile radius around the stations. Regional and corridor roadway operations were evaluated using six screenlines that assessed transit and vehicle travel performance in key subareas through the study area. As described in the transit section of this chapter (3.4), Sound Transit and King County Metro (Metro) service planners reviewed future bus routes as part of this project.



A **screenline** is an imaginary line across a section of freeways or arterials. These screenlines are used to provide a snapshot of how much volume is entering or exiting a particular area.

3.1.2 Meeting the Need for the Project

As summarized in the following points, the analysis in this chapter demonstrates that the East Link Project would meet and exceed the need for the project in all the categories presented in Chapter 1:

- **Increased Demand for Transit Services.** Without East Link, existing and projected transit service would not meet transportation reliability and capacity needs for the Eastside corridor. Projected residential and employment growth is expected to double the demand for transit services across Lake Washington and between Bellevue and Redmond by 2030 with the No Build Alternative, further highlighting the importance of providing reliable transit service. The East Link Project would more than double the I-90 person capacity across Lake Washington without any roadway widening.

East Link Project

Being able to move more people in both directions, especially in the reverse-peak direction (eastbound in the morning [AM] and westbound in the afternoon [PM]), when travel times are expected to double in the future, would improve the mobility into and out of the urban centers (Seattle, Bellevue, Overlake, and Redmond) on both sides of Lake Washington that this project would serve.

East Link would meet a growing demand for reliable transit alternatives. Within the East Link corridor, the travel mode in the future is predicted to shift, generally reducing the percentage of single-occupant vehicles (SOVs) and increasing the percentage of high-occupancy vehicles (HOVs [vanpools and carpools]) and transit (buses and light rail), a mode that carries more people within the limited transportation space. With the project, transit ridership across Lake Washington would increase by about 25 percent compared with the no-build condition during the PM peak period; therefore, an estimated 16 percent of the total number of people traveling across the lake would be in transit. This shift to transit indicates the growing demand for reliable high-capacity modes of travel that are consistent with urban environments and are crucial to providing person mobility rather than vehicle capacity.

- **Increased Congestion on I-90.** The vehicular capacity of I-90 during the peak periods is expected to be reached within the near future (around year 2015) (Washington State Department of Transportation [WSDOT], 2006). This would further constrain travel for all modes, including freight, HOVs, and buses. In addition, roads leading into and out of the urban centers of Seattle and Downtown Bellevue are forecasted to be at or near capacity in the near future, increasing travel time between these two key employment and population centers. This would substantially constrain the ability to travel to key employment and population areas of the region and highlights the need for increased transit service, which provides greater capacity and is more reliable than SOVs. Light rail also provides a safer transportation alternative because it operates in its own right-of-way for most of the project.
- **Regional Urban Center Growth Plans Supported by High-Capacity Transit Investments.** In accordance with Puget Sound Regional Council's (PSRC's) adopted *Transportation 2040* plan (PSRC, 2010) and the Growth Management Act objectives, Bellevue, Seattle, and Redmond have made land use and planning decisions for increased employment and residential density based in part on the long-term promise of high-capacity transit (HCT) connections across I-90. Traffic projections indicate that most major roadways in the study area would be congested and would fail to move vehicles effectively by 2030. This would occur even with implementation of planned transportation improvements on SR 520, I-90 (without East Link), and I-405. With the East Link Project, HCT would connect the region's dense commercial and residential centers, as well as major employers, across Lake Washington without being hindered by the increasingly congested highway conditions.
- **Operating Deficiencies in Regional Bus Transit.** The travel time between the key urban centers of Seattle and Downtown Bellevue would improve with light rail because light rail is faster and more reliable than bus or automobile. The East Link Project analysis estimates that light rail travel between Seattle and Downtown Bellevue would take less than 20 minutes, and between Seattle and Downtown Redmond, 29 to 39 minutes, regardless of time of day or level of traffic congestion. This is a savings of up to 25 minutes compared with an automobile currently traveling between these locations—in the afternoon peak period it currently can take approximately 45 minutes to travel between Seattle and Bellevue (via I-90) and approximately 55 minutes to travel between Seattle and Redmond (via SR 520) (WSDOT, 2011). In the future, these automobile times are expected to continue to rise, and therefore light rail would provide an even greater travel-time savings.

  Light rail service to the Eastside would substantially improve transit service reliability throughout the project vicinity. It is expected that bus reliability in the future would continue to operate at failing levels (not meeting level of service [LOS] standards) without the project, and a majority of the bus routes would not meet scheduled headways (the time between bus arrivals). Buses would continue to be an unreliable travel choice in the project area, for instance across Lake Washington and in Downtown Bellevue and

Traffic Level of Service

Describes traffic conditions in terms of speed and travel time, freedom to maneuver, comfort, convenience, and safety. LOS A is considered to be the ideal "free-flowing" condition, while LOS F is considered to be the least desirable condition, with stop-and-go traffic.

Redmond, because bus service would be slowed by heavily congested roadways. Bus speeds between Downtown Seattle and Downtown Bellevue are predicted to decrease approximately 30 percent by year 2030 as congestion worsens, even with improvements to I-90, because arterials connecting I-90 to these urban centers would not be improved. This poor bus reliability would not benefit transit ridership and would not provide an attractive transportation choice for the region.

The frequency of transit throughout the day would also improve because light rail would arrive every 15 minutes or less, in comparison with buses arriving on average every 30 minutes or more during off-peak hours. Light rail would also serve more hours of the day with expanded service coverage of 20 hours—a substantial improvement over existing and planned bus service.

- **Limited Transit Capacity and Connectivity.** Light rail service not only provides increased service frequency, faster travel times, and longer hours of service throughout the day, it would also be able to carry more passengers to connecting bus routes. The bus routes that share connections with the light rail system would likely experience higher ridership. By the year 2030, approximately 10,000 new riders would choose to ride transit each day with the addition of light rail serving Eastside communities. Overall, the East Link Project is forecasted to contribute between 48,000 and 52,500 daily riders to the region's light rail system. This is expected to eliminate close to 230,000 vehicle miles traveled and about 10,000 hours of travel each day in the region in 2030.

  The East Link light rail project has the capacity to carry from 9,000 to 12,000 people per hour in each direction, which would more than double the person-carrying capacity of I-90. The ability to carry this many people is equivalent to about seven to ten freeway lanes of vehicle traffic. Without light rail's ability to move more people in both directions across Lake Washington, there would continue to be roadway capacity constraints that would not efficiently and reliably serve the growing residential and commercial land use densities on the Eastside.

3.2 Methodology and Assumptions

The transportation impacts of the East Link Project were analyzed from three different perspectives: regional, corridor, and operations. The regional and corridor assessments addressed larger areas in the overall project vicinity. The operational assessment identified and analyzed specific roadways and intersections. The following types of information were developed and evaluated in these three analysis areas:

- Regional analysis includes information such as projectwide ridership and daily vehicle miles and hours of travel.
- Corridor analysis includes information such as transit service and ridership, roadway volume-to-capacity (v/c) ratios, and mode share.
- Operational analysis includes information on the operations (traffic LOS) and safety of the highways, arterial and local streets, and intermodal network(s).
- The arterial and local street analysis focused on intersection operations and safety analysis, whereas the highway analysis focused on person throughput and capacity, travel time, and safety. Impacts on parking, nonmotorized facilities, transit, and freight movement were also addressed. Construction impacts on traffic circulation were assessed qualitatively for local traffic and quantitatively for I-90.

The methodology and assumptions that were used to analyze the project impacts are discussed in detail in Appendix A of the *Transportation Technical Report* (see Appendix H1 of this Final EIS). That appendix includes further information on the following topics:

- Agency guidelines and regulations regarding the analysis of local and regionwide project impacts
- Transportation analysis methodology, including relevant definitions, data collection, regional traffic analysis, corridor traffic analysis, intersection impact analysis, and construction impact analysis
- Methods for traffic forecasting and assessing local and projectwide LOS standards and safety
- Methods for assessing impacts related to light rail station and park-and-ride areas, parking, nonmotorized facilities and modes, property access circulation, freight, transit, and construction.

3.3 Regional Travel

3.3.1 Methodology

This section describes the project's existing conditions (year 2007) and potential project impacts on regional transportation facilities in the study area in years 2020 and 2030. Regional travel conditions for the East Link

Project were evaluated based on future travel information obtained using the PSRC transportation demand model and Sound Transit's transit ridership model, which includes the urbanized areas of King, Pierce, and Snohomish counties. These travel demand models were used to create 2020 and 2030 vehicle and transit ridership forecasts for the study area. Based on these forecasts and driver travel patterns, the number of miles and hours traveled were estimated to create vehicle miles traveled (VMT) and vehicle hours traveled (VHT). On roadways in the study area, the vehicle traffic and mode share were predicted, giving the v/c ratios (congestion) and mode share at each of the six project screenlines shown in Exhibits 3-1 through 3-3.

Vehicle Miles Traveled (VMT). The total number of miles traveled each day by drivers in the region.

Vehicle Hours Traveled (VHT). The total number of hours that people drive each day in the region.

Volume-to-Capacity (v/c) Ratio. The ratio of how many vehicles are on a road compared to that road's capacity. A v/c ratio between 0.90 and 1.0 indicates slow traffic conditions, a v/c ratio between 1.0 to 1.2 indicates stop-and-go conditions, and a v/c ratio over 1.2 indicates severe traffic congestion.

Mode Share. The percentage of people using different travel modes (methods) such as single-occupant vehicles, high-occupancy vehicles (HOVs), and transit.

3.3.2 Affected Environment

3.3.2.1 Vehicle Miles Traveled and Vehicle Hours Traveled

In the Puget Sound region, vehicles travel more than 70 million miles each day. This results in close to 2 million hours of travel for all users of the transportation system. In the AM peak period (6 to 9 a.m.), daily regional travel is about 12 million total vehicle miles and over 300,000 total vehicle hours. In the PM peak period (3 to 6 p.m.), there are about 15 million total VMT and over 400,000 total VHT daily. Thirty-seven percent of all miles traveled and more than 40 percent of all hours of travel occur in the AM peak and PM peak periods, indicating that the most congested periods in this region are during the AM and PM commuting periods. Within the morning and afternoon peak periods, the highest hour of congestion is known as the AM and PM peak hours. Depending on the type of analysis, the performance measures used are based on either the peak period or the peak hour. The major regional highways within the East Link study area are I-90, I-5, I-405, and SR 520, and these highways serve a substantial amount of the vehicle trips within the Central Puget Sound region. SOVs were the dominant mode of regionwide travel in year 2006, accounting for 44 percent of the trips made. A large number of trips also occurred in vehicles with two or more passengers (HOV). Together, SOV and HOV travel accounted for 84 percent of the person trips made in 2006. The remaining trips were by transit, walk, and other modes (PSRC, 2007). The primary transit service providers within the project vicinity are King County Metro, Sound Transit, and Community Transit.

3.3.2.2 Regional Highways

I-90 is a major east-west interstate highway that extends from Boston through Chicago, and ends in Seattle at I-5, the western portion of the East Link Project corridor. In Washington, I-90 connects various freight and state routes originating in Seattle, through Mercer Island and Bellevue, to the eastern side of the state and beyond. The section of I-90 that crosses Lake Washington, including the floating bridges (Lacey V. Murrow Memorial Bridge and Homer M. Hadley Memorial Bridge), has three general-purpose lanes in each direction and a reversible center roadway that operates as a westbound expressway during the morning and as an eastbound expressway during the afternoon and evenings. The reversible center roadway is currently used for HOVs, buses, and Mercer Island drivers. These reversible lanes are located between the Mount Baker Tunnel in Seattle and the Bellevue Way SE interchange. On the floating bridges, the average daily traffic volume is 140,000 to 150,000 vehicles. This consists of about 135,000 vehicles per day in the eastbound and westbound mainline lanes and about 15,000 daily vehicles in the reversible center roadway (WSDOT, 2007).

I-5 is the primary north-south West Coast route in the region, connecting the U.S. borders with Canada and Mexico. In Washington, this interstate is a major transportation corridor in the Puget Sound region and serves as a main highway connection among the urban communities between Portland and Seattle.

I-405 is a key interstate facility that parallels I-5 on the east side of Lake Washington and connects to I-5 in Tukwila and Lynnwood. I-405 has interchanges that connect with I-90 and with state routes. In urban areas of the project corridor, specifically Downtown Bellevue, I-405 consists of six lanes with HOV facilities.

SR 520 provides an east-west connection across Lake Washington between Seattle and the Eastside communities, such as Kirkland, Bellevue, and Redmond, and connects large employment centers in Bellevue, Redmond, and Seattle.

3.3.2.3 Screenline Performance

A v/c ratio of 0.90 and above indicates slow to severe traffic conditions. Screenline 2, which crosses I-90 and SR 520 (see Exhibit 3-1), and Screenline 4, which crosses I-405 (see Exhibit 3-2), cross areas of heavy congestion in both directions in the peak periods, as indicated by a v/c ratio above 1.0. This level of congestion is expected because these screenlines intersect three of the most heavily traveled highways in the region (SR 520, I-90, and I-405). Most of the other screenlines have a v/c ratio less than 0.70. Although Screenline 3 (Exhibit 3-2) is also located on I-90, its v/c ratio is considerably less than at Screenline 2 because of the additional roadway capacity (collector-distributor system) that is provided between Bellevue Way and I-405 to better manage the flow of traffic.

Within the study area, the current use of different transportation modes (mode share) varies depending on available transportation choices, congestion, and land use (e.g., commercial, residential, retail) surrounding the area. For example, some of the higher HOV and transit mode shares are found at locations leaving Seattle (Screenline 1 southbound and screenlines 2 and 3 eastbound). At Screenline 5 (Exhibit 3-3) westbound and Screenline 6 southbound (these routes include trips to Seattle across SR 520), a higher HOV mode share occurs compared with its counter eastbound direction into Redmond.
Exhibit 3-4 shows the existing mode share during the PM peak hour at each screenline.

3.3.3 Environmental Impacts

This section describes the potential regional travel impacts associated with the No Build Alternative and with the proposed East Link Project. The analysis shows that the East Link Project would reduce the rate of growth of regional VMT and VHT, lower v/c ratios at the screenlines, and produce a mode share with an increased emphasis on transit. The *Transportation Technical Report* provides a more detailed year 2020 and 2030 discussion of the regional VMT and VHT, v/c ratios, and mode share.

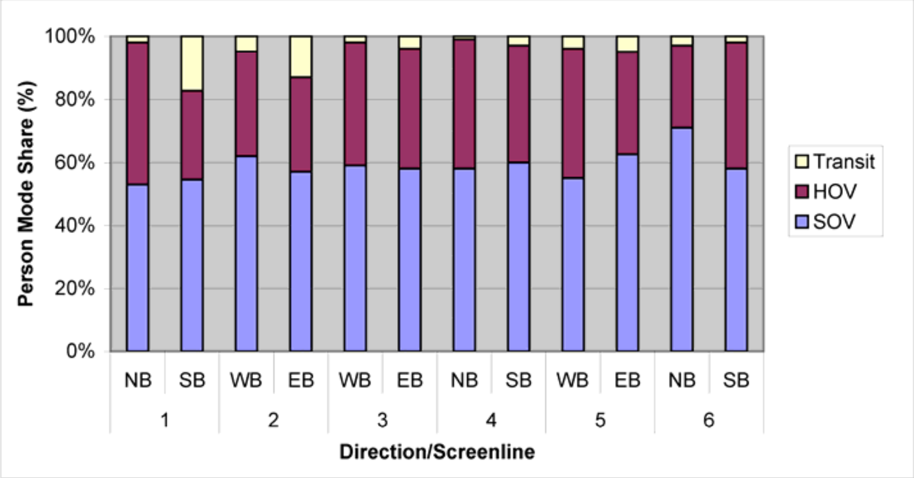
3.3.3.1 Traffic Forecasts

Future-year analysis was based on PSRC's current population and land uses forecasts for years 2020 and 2030 in the regional travel demand model. The programs and/or projects that were assumed in the analysis to occur in the future, both with and without the East Link Project, were selected because they are considered reasonably foreseeable. These projects include a mixture of state highway and local roadway projects as well as Sound Transit and Metro enhancements. Attachment 1 in Appendix A of the *Transportation Technical Report* gives a complete list of future projects that were assumed to occur in the future.

According to PSRC's regional trip forecasting and regional population and employment forecasts, travel on major highway facilities will continue to increase through 2030. Future roadway projects will improve the HOV system, allowing more carpool trips, but will not include substantial improvements in high-capacity modes of travel. Roadways that lead into and out of the urban centers of Seattle and Downtown Bellevue will be at capacity in the near future. Exhibit 3-5 depicts PSRC's 2030 PM forecast without East Link for roadways with a v/c ratio of greater than 0.90, meaning slow to severe traffic conditions. This exhibit shows that, in 2030, the afternoon commute across Lake Washington on SR 520 and I-90 and on I-5 and I-405 will range from slow, to stop-and-go, to severe traffic conditions.

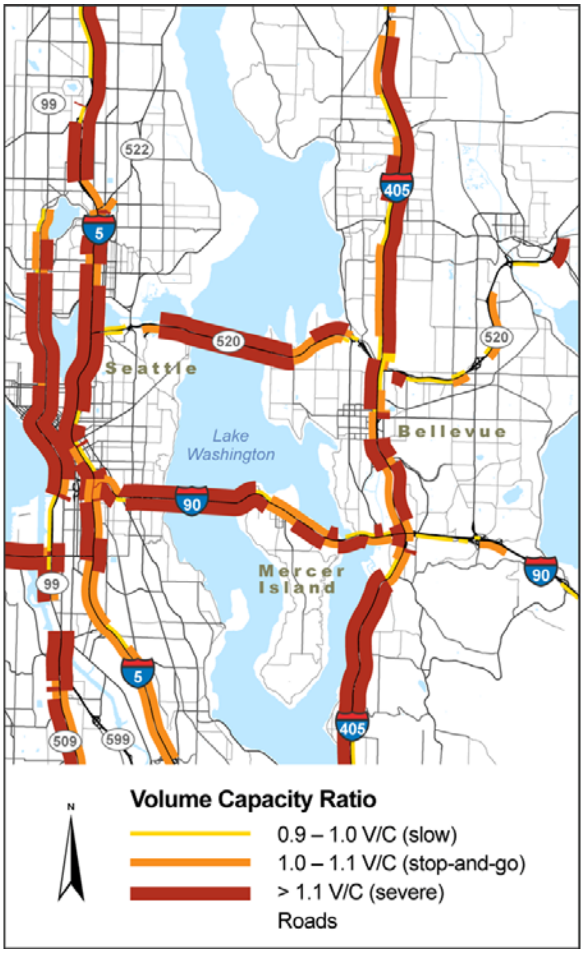
This congestion would substantially constrain the ability to travel into key employment and population areas of the region and highlights the importance of increased utilization of transit.

The East Link Project would link Seattle, the region's main urban downtown area, with the Eastside communities, connecting the region's dense commercial and residential centers as well as major



HOV = high-occupancy vehicle
SOV = single-occupant vehicle

EXHIBIT 3-4
Existing PM Peak-Hour Screenline Mode Share



Source: PSRC, 2007

EXHIBIT 3-5
PSRC 2030 PM Highway Volume-to-Capacity Ratios without East Link

employers across Lake Washington. Light rail would support increased density in Bellevue and Redmond, as well as Seattle, consistent with regional land use plans and Washington Growth Management Act goals to preserve natural resources. Higher density provides economic growth and opportunities for more effective infrastructure development with HCT. Travel between the key urban centers (Seattle and Downtown Bellevue) would improve with light rail service because it has greater capacity and is a more reliable mode of travel than SOVs.

Year 2020 and 2030 annual traffic growth rates for the PM peak hour are listed in Table 3-1. These are based on PSRC travel demand model forecasts. By year 2030, the annual vehicle growth rates within the study area would be less than 2 percent per year. With East Link, a slight reduction in auto usage is forecasted as approximately 10,000 people shift their mode of transportation and use light rail by year 2030.

TABLE 3-1
Future PM Peak-Hour Traffic Growth Rate for No Build Alternative

Segment	Boundary	Annual Vehicle Growth Rate (percent) Year 2020	Annual Vehicle Growth Rate (percent) Year 2030
Segment A	Seattle to South Bellevue	2.5	1.8
Segment B	South Bellevue to Bellevue Central Business District	0.8	1.0
Segment C	Bellevue Central Business District	1.3	1.7
Segment D	Bellevue Central Business District to NE 40th (Redmond)	2.5	1.9
Segment E	NE 40th (Redmond) to Downtown Redmond	1.7	1.5

3.3.3.2 Vehicle Miles Traveled and Vehicle Hours Traveled

VMT and VHT are regional performance measures used to assess the impacts of the project alternatives on travel. Changes in VMT mean people are traveling either less or more distance (miles) to get to their destinations. Changes in VHT generally reflect the change in traffic congestion or the amount of time required to travel.

The PSRC and Sound Transit travel demand models were used to predict traffic conditions with the East Link Project. The results indicate that the regionwide VMT and VHT would decrease by about 0.20 percent, with the majority of the reductions occurring in the AM and PM peak periods. This is a reduction of slightly less than 230,000 VMT and 10,000 hours of travel each day in year 2030. Total regional VMT and VHT for year 2030 with and without East Link are shown in Table 3-2.

TABLE 3-2
2030 Regional Travel Impact Comparison Summary

	No Build	East Link	Percent Change
Total VMT	116,690,200	116,461,200	-0.20
Total VHT	4,463,000	4,453,900	-0.20

Source: PSRC and Sound Transit demand models.

3.3.3.3 Screenline Performance

Generally, with the project, regional roadway v/c ratios would remain the same or improve slightly (lower values) compared with the No Build Alternative. Removing vehicle use from the center roadway to accommodate light rail would not affect other regional highways, such as SR 520, I-5, and I-405. Mode shares generally would become less dominated by SOVs as the transit share increases. With the project, transit ridership across Lake Washington would increase by about 25 percent compared with no-build condition during the PM peak period; therefore, an estimated 16 percent of the total number of people traveling across the lake would be using transit. This mode shift provides increased person mobility in a corridor with limited opportunities for road expansion. The projected v/c ratios and mode shares are summarized in this section for each screenline. Year 2030 v/c ratios at each screenline are shown in Table 3-3. Exhibit 3-6 shows the PM peak-hour mode share at each screenline for year 2030.

TABLE 3-3
2030 PM Peak-Hour Volume-to-Capacity Ratios at Screenlines

Screenline	Direction	2030	
		No Build[a]	East Link
1	Northbound	0.95	0.94
	Southbound	1.16	1.14
2	Westbound	1.13	1.12
	Eastbound	1.02	1.17
3	Westbound	0.70	0.68
	Eastbound	0.82	0.72
4	Northbound	1.12	1.10
	Southbound	1.22	1.23
5	Westbound	0.75	0.75
	Eastbound	0.77	0.78
6	Northbound	0.86	0.86
	Southbound	.059	0.58

Source: PSRC travel demand model.

[a] No-build condition with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.

Screenline 1: City of Seattle

For the No Build Alternative, the mode share among SOV, HOV, and transit usage in Seattle (across Screenline 1) is expected to change little in the future. With East Link, transit usage would more than double, and the Screenline 1 v/c ratios would improve. This increase in transit share is due to modifications in transit service and the addition of light rail service across this screenline.

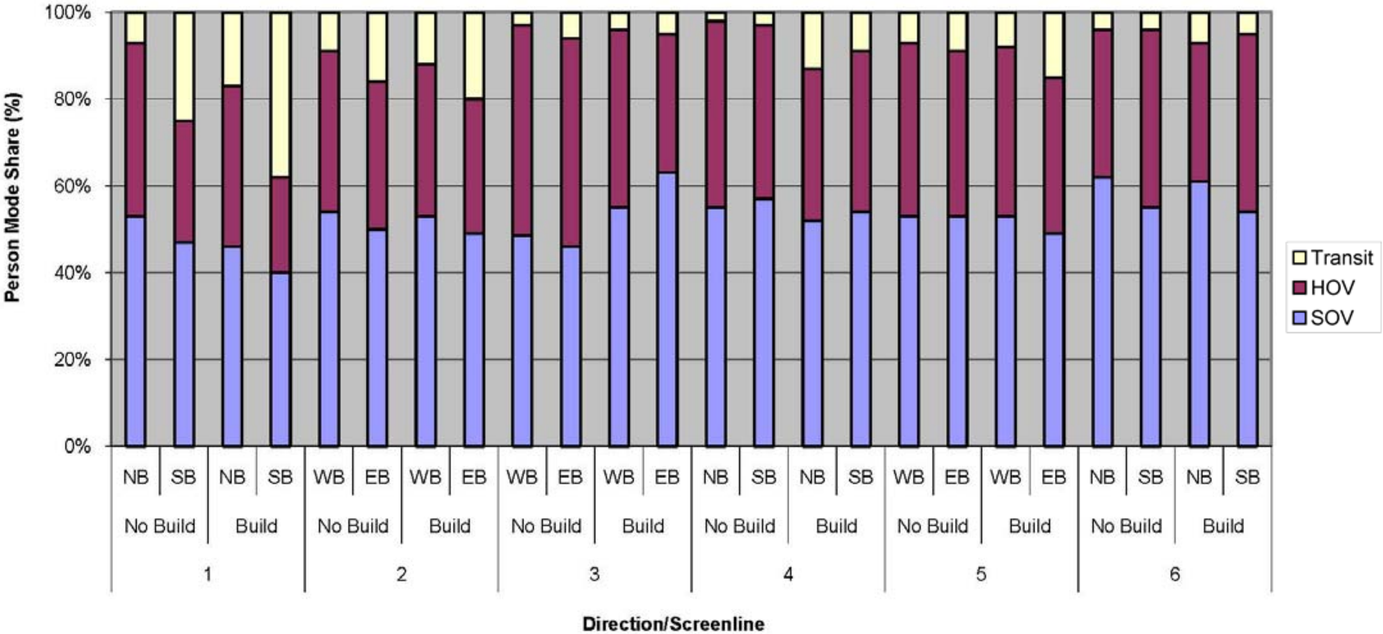
Screenline 2: Lake Washington (Includes I-90 and SR 520)

In the future, the v/c ratios crossing Lake Washington on both I-90 and SR 520 (across Screenline 2) would remain similar to today's highly congested conditions with or without light rail. Because the I-90 reversible center roadway would be removed by the East Link Project, the v/c ratio in the peak directions (into Seattle in the morning and out of Seattle in the afternoon) is expected to become slightly higher than with the No Build Alternative, although increased transit use with the project would increase person throughput and provide increased capacity for future growth (see Section 3.5.3.3). Forecasted travel on both I-90 and SR 520 with the East Link Project is expected to remain similar to the No Build Alternative, indicating no substantial diversion to other facilities.

For travel across Screenline 2 in 2020 and 2030, the percentage of SOVs would slightly decrease with the No Build Alternative as congestion worsens and people choose alternative modes, such as HOVs and transit. With light rail, both SOV and HOV usage would decrease as people choose to use transit. Providing light rail would increase transit usage in 2030 by up to 25 percent, which is a substantial shift to transit. There is also an expected slight shift in HOV usage from I-90 to SR 520. This shift would be caused in part by the planned SR 520 HOV lane improvements and closure of the I-90 center roadway. Section 3.5 discusses I-90 traffic operations and congestion patterns in detail, including vehicle and person throughput, vehicle travel time, level-of-service, and safety.

Screenline 3: Interstate 90 (at Mercer Slough)

With the No Build Alternative, congestion in the future would increase slightly compared with existing conditions. With the East Link Project, v/c ratios across Screenline 3 would decrease slightly because of a shift in travel patterns during the PM peak hour, indicating that congestion would improve slightly. Mode shift patterns indicate that, with the future No Build Alternative, SOV usage would decrease and HOV and transit usage would increase. With light rail, the HOV share would decrease slightly due to the reasons noted above for Screenline 2.



Note: No-build condition with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.

EXHIBIT 3-6
2030 PM Peak-Hour Mode Share at Screenlines

Screenline 4: South Bellevue

In 2020 and 2030 with the No Build Alternative, v/c ratios at Screenline 4 are expected to be near or above 1.0. This indicates that future travel into and out of the key Eastside urban center of Downtown Bellevue would remain constrained. With the East Link Project, congestion would improve slightly, but v/c ratios would still be at or over capacity. The percentage of people using SOVs, HOVs, and transit at this location is expected to remain fairly similar between existing conditions and the No Build Alternative. With light rail, the transit mode share would increase substantially as people adjust their travel patterns and choose to use light rail to travel into and out of Bellevue. Overall, by 2030 the transit share of total trips is expected to reach over 10 percent with light rail. This is a substantial increase from the 2 to 3 percent transit share in the No Build Alternative. This increase in transit share is due to the addition of light rail service across this screenline. For a discussion of cross-lake mode share, refer to the Screenline 2 (Lake Washington) discussion above.

Screenlines 5 and 6: Bellevue-Redmond (Bel-Red) and Redmond (Grasslawn)

Across screenlines 5 and 6, future v/c ratios are expected to increase and further constrain vehicle travel with the No Build Alternative. With East Link, v/c ratios would either remain similar or slightly decrease as people use light rail. Mode share percentages for the No Build Alternative would remain similar to existing conditions, with approximately 55 to 65 percent SOV vehicle users and 30 to 40 percent HOV users. With East Link, transit is expected to increase to 7 percent of the total mode share.

3.3.4 Potential Mitigation

No mitigation would be required for regional travel impacts because, overall, the highways and arterials would not experience adverse changes in operations. The v/c ratios and mode share would generally remain similar or would improve with the East Link Project. For specific mitigation along I-90, refer to Section 3.5.

3.4 Transit

3.4.1 Methodology

The six screenlines established for evaluating the East Link Project, along with the areas served by the project, were used to measure the transit LOS performance (buses and light rail) along key corridors within the study area (see Exhibits 3-1 through 3-3 for the screenline locations). The project alternatives include both light rail and bus service on the Eastside, whereas the No Build Alternative includes only bus service on the Eastside. The bus routes that were selected for evaluation are those most likely to have their ridership influenced by the project.

The impacts on existing and future regional and local transit services were evaluated based on the following categories:

- Coverage and circulation
- Transit LOS performance
  - Service frequency LOS
  - Hours of service LOS
  - Passenger load LOS
  - Reliability of service LOS
- Transit travel time
- Transit transfers
- Light rail ridership

The coverage area is defined as the area(s) for which transit provides service. Circulation is defined as the route(s) on which transit operates. Transit LOS performance was analyzed for the PM peak hour (5 to 6 p.m.) to describe transit performance during the period when traffic congestion and transit ridership are highest. For transit LOS performance, LOS A indicates more frequent service, more hours served during the day, high reliability, and minimal passenger crowding in a transit vehicle. LOS F indicates less frequent service, fewer hours served during the day, low reliability, and passenger crowding in a transit vehicle. Individual components of transit LOS performance are defined as follows:

- Service frequency LOS is the number of times within the PM peak hour that a bus or light rail train stops at a specific location. Generally, the less time riders have to wait between bus arrivals, the better the service frequency LOS. Bus routes that have headways less than 10 minutes are considered LOS A, whereas more than 60-minute headways are LOS F.
- The hours of service LOS measures the total number of transit operating hours provided within a 24-hour (daily) period. Hours of service LOS is intended to measure the availability of transit service to riders and potential users. The longer the period that transit service is provided throughout the day, the better the LOS.
- The passenger load LOS, which is measured at screenlines, is intended to measure passenger comfort and the ability of a rider to find a seat during the on-board portion of the trip during the PM peak hour. Passenger load LOS also measures crowding in the transit vehicle. A passenger load LOS at or worse than LOS D may reflect overcrowding, and, therefore, the transit service provider could consider service changes, such as increasing the transit frequency. In addition, a large number of passengers can cause the bus to wait (dwell) longer at stops because of crowded passenger boarding and alighting. A longer dwell time can negatively affect travel time and service reliability.
- Service reliability LOS was analyzed at major transit hubs along the East Link route. The reliability LOS measures the degree to which a transit vehicle meets or misses its scheduled headway at its arrival station. The routes evaluated at each major transit hub were chosen using the same criteria as the routes used in passenger load LOS evaluation. Two methods were used to determine transit reliability. For transit routes with scheduled headways greater than 10 minutes, on-time reliability was analyzed in terms of on-time performance, defined as being 0 to 5 minutes late. For transit routes operating at scheduled headways of 10 minutes or less, headway adherence was used to determine reliability. Headway adherence reliability was calculated comparing actual headways with scheduled headways of transit routes at major transit centers and park-and-ride lots within the study area. Future on-time performance and headway adherence for buses was not forecasted, so future bus reliability LOS was based on existing conditions. It was assumed that both Metro and Sound Transit would adjust their bus services according to the demand and congestion levels to maintain existing reliability, although unforeseen conditions may limit what is implemented.

Transit Level of Service. Transit conditions, such as delays at intersections, that influence how passengers perceive the quality of a transit trip. Measures of transit LOS include:

Transit Coverage. The areas for which transit routes provide service.

Service Frequency. How often the bus arrives at scheduled stops.

Transit Headway. The length of time between transit vehicles arriving at a location.

Hours of Service. How many hours the transit route operates in a day.

Passenger Load. How full a transit vehicle is compared to its capacity.

Transit Reliability. How often the transit vehicle arrives on time at its scheduled stops.

Alighting. Transit passengers exiting the transit vehicle.

From a bus rider's perspective, all individual bus routes that serve two areas can sometimes be perceived as a single service between these two areas. To reflect these connections, pairs of specific areas served by East Link were evaluated. These areas are Northgate, University District, Downtown Seattle, Mercer Island, South Bellevue, Downtown Bellevue, Bel-Red, Overlake, and Downtown Redmond. Transit performance of these area connections was evaluated for service frequency LOS and hours of service LOS.

The *Transportation Technical Report*, located in Appendix H1 of this Final EIS, provides a detailed discussion of the routes within the study area as well as the transit LOS performance analysis methodology.

3.4.2 Affected Environment

Within the study area, transit services, including regional express buses and local buses, are provided by Metro, Sound Transit, and Community Transit. The frequency and number of bus routes in service increases during the peak periods (6 to 9 a.m. and 3 to 6 p.m.), most noticeably in the peak direction of travel (into employment areas in the AM, exiting employment areas in the PM). Sound Transit and Metro transit services crossing Lake Washington and connecting Downtown Seattle to Downtown Bellevue, Overlake, and Downtown Redmond currently serve over 13,000 transit riders (King County Metro, 2008a).

Major transit activities within the study area occur at transit centers and park-and-ride lots. A transit center is a central transportation hub where transportation modes and routes meet, providing transit users a central location to connect with multiple transit services and providers. There are four transit centers within the study area: International District/ Chinatown Station, Bellevue Transit Center, Overlake Transit Center, and Redmond Transit Center.

A park-and-ride lot is a parking facility in which people can park their vehicles and transfer to other modes (e.g., bus, rail, carpool, nonmotorized) to travel to destinations, mainly urban centers (e.g., Downtown Seattle, Bellevue). There are park-and-ride lots in segments A, B, D, and E. Metro and Sound Transit provide service to transit centers and park-and-ride lots so riders can make transfers to reach their destinations. Within the study area, Community Transit provides service only to the Overlake area. Table 3-4 lists the existing transit facilities in the study area.

TABLE 3-4
Existing Transit Facilities in Study Area

Transit Facility	Type of Facility	Served by Routes[a]	Park-and-Ride Stalls[a]
International District/Chinatown Station	Station	KCM 41, 71, 72, 73, 74X, 101, 106, 150, 174, 194, 212, 217, 225, 229, 255, 256, 301 ST 550	none
Bellevue Transit Center	Transit center station	KCM 220, 222, 230, 232, 233, 234, 237, 240, 243, 249, 253, 261, 271, 280, 342, 630, 885, 886, 921 ST 532, 535, 550, 555, 556, 560, 564, 565	none

[a] Transit routes and park-and-ride stalls as of spring 2007 except for Mercer Island Park-and-Ride lot, which was inventoried in February 2008 (King County Metro, 2008b).

CT	Community Transit
KCM	King County Metro.
ST	Sound Transit

Sound Transit's Regional Express buses provide regional transit service to commuters within the study area as well as in other parts of King County and Pierce and Snohomish counties. Average headways of buses within the study area are 30 minutes. A few Sound Transit routes (such as ST 550 between Bellevue and Seattle) offer more frequent service, with headways around 10 minutes. In Downtown Seattle, Sound Transit also offers other services, including the Sounder commuter rail and Central Link light rail. The International District/Chinatown Station, a bus and Central Link station in the downtown Seattle Transit Tunnel, provides a connection to Sounder and Amtrak services at the nearby King Street Station. Sounder operates during peak periods with train service between Seattle and Tacoma and between Seattle and Everett. Central Link light rail offers light rail service between Downtown Seattle and the Seattle-Tacoma International Airport (Sea-Tac Airport). Headways for the light rail line are currently 7.5 minutes in each direction during the peak periods.

Metro provides regional and local service throughout King County. Within the study area, Metro operates most of the local fixed-route and express bus service in addition to other transit services. During peak periods, the average headway for Metro buses is about 30 minutes. Community Transit provides service between Snohomish and King counties and has one bus route within the study area.

3.4.3 Environmental Impacts

The East Link Project would improve transit operations and LOS within the regional transit system. Light rail would provide regional travel benefits by extending transit access and mobility into the growing urban areas east of Lake Washington. Enhancing transit service connections with light rail between major employment centers in the Puget Sound region—Seattle, Bellevue and Redmond—would improve overall transit usage by providing these communities with more reliable transit service.

By 2030 with this project, between 48,000 and 52,500 riders would use East Link, and slightly over 10,000 more people would use transit compared to the no-build condition where only bus service is provided to the Eastside communities. These people would not use transit if this project is not built. Light rail would provide service between Seattle and Downtown Bellevue in under 20 minutes and between Seattle and Redmond in 29 to 39 minutes. Light rail service would close gaps in the existing transit network. Bus routes that share connections with the light rail system would likely experience higher ridership, while light rail would be able to carry an increased number of passengers to connecting bus routes. As further described in this section, light rail would improve transit service by providing increased service frequency, faster travel times, and longer hours of service throughout the day, in addition to serving both the peak and reverse-peak directions.

3.4.3.1 Coverage and Circulation

Sound Transit and Metro service planners developed a bus service plan for the 2020 and 2030 years for both the No Build and the East Link alternatives. Although the service plans would not be finalized until close to system operation, the plans provide a snapshot of how bus service would look with and without the project. Some of these plans are currently being implemented through Transit Now, an initiative to expand Metro service that was approved by King County voters in the general election in November 2006, and Sound Transit's ST2 program approved by King, Snohomish, and Pierce County voters in the November 2008 general election.

In general, the future bus service frequency and coverage area would increase both with and without the East Link Project because of changes in travel demand patterns and regional growth. With the project, bus service within the study area would change to feed the light rail system: some routes would be modified to end at the light rail stations where bus layover areas would be provided, and other routes would continue from the stations. Bus routes that serve the same markets as light rail and that are far less reliable would be reduced or eliminated. The following subsections briefly describe transit coverage and circulation changes associated with the project alternatives in each of the project segments. For more detailed information please refer to Section 4.3.1 and Appendix C of the *Transportation Technical Report.*

Segment A, *Preferred Interstate 90 Alternative (A1)*

Along I-90 between Seattle and the Bellevue Way interchange, light rail would use the reversible center roadway. Peak direction buses would be rerouted from the reversible center roadway to the HOV lanes in the outer roadways constructed as part of the I-90 Two-Way Transit and HOV Operations Project. Bus access to and from Mercer Island and the Rainier Avenue flyer stop would be maintained in all directions with a combination of the existing ramps provided on the outer roadways and the future HOV lanes and ramps built as part of the I-90 Two-Way Transit and HOV Operations Project. East of I-405, the I-90 HOV lanes and transit access that currently exists would not change with the East Link project. Changes to key transit routes on I-90 east of I-405 are further described in this section and are included in the transit LOS and ridership forecasts, where applicable.

In Seattle, if the D2 Roadway (the ramp connection between I-90 at Rainier Avenue S and the Airport Way S and 5th Avenue S intersection) is not designated as joint use for buses and light rail, Downtown Seattle bus routes that use the D2 Roadway would more than likely be rerouted to 4th Avenue S via SR 519. Sections 3.4.3.2 and 3.5.3.3 identify the bus reliability and bus travel times with and without joint use operations on the D2 Roadway, respectively. Also in Seattle, as evaluated in the North Link Supplemental Final EIS (Sound Transit, 2006), buses might not operate in the Downtown Seattle Transit Tunnel once light rail extends to Northgate, which is an assumption for the East Link No Build Alternative and project alternatives for both 2020 and 2030 years.

Direct transit service between Mercer Island and the University District would not occur in the No Build Alternative because the bus route that connects these areas would be deleted per the future bus service plan. With East Link, the direct connection between these areas would be reestablished via light rail. Additional connections would also be created with light rail between Mercer Island and Northgate, Bel-Red, Overlake, and Downtown Redmond.

With the project, Sound Transit Regional Express Route 554 (ST 554) would be assumed to terminate at the Mercer Island Station. With this change, bus stops would be relocated on Mercer Island to serve ST 554 when it arrives from the east. Route ST 550 would also be eliminated because it would provide parallel service to light rail.

On Mercer Island, if the future eastbound HOV off-ramp is not connected to 77th Avenue SE (connecting to Island Crest Way is Sound Transit's and WSDOT's preferred configuration), buses traveling eastbound on I-90 would continue to be able to serve the Mercer Island Park-and-Ride via the general-purpose eastbound off-ramps similar to current eastbound I-90 bus operations when the center roadway is closed to eastbound traffic.

Segment B

Under the No Build Alternative, direct transit connections to South Bellevue would not change. With light rail, however, South Bellevue would be directly connected to the Bel-Red, Overlake, Downtown Redmond, Northgate, and University District areas.

Preferred 112th SE Modified Alternative (B2M)

Under the *Preferred Alternative B2M*, route ST 550 would be eliminated, and other bus routes would continue to serve Bellevue Way between the South Bellevue Park-and-Ride and the Bellevue Transit Center. All other modifications to the future transit service coverage and circulation for Segment B would be similar in the no-build and build conditions.

Other Segment B Alternatives

For the BNSF Alternative (B7) at the 118th Station, some bus routes that could be effectively rerouted would begin and end at this station. Without the project, many of these routes would begin and end at the Wilburton Park-and-Ride. Current bus service on Mercer Island would connect to the South Bellevue Park-and-Ride and Downtown Bellevue with Alternative B7. For all other Segment B alternatives, transit service coverage and circulation would remain similar to the *Preferred Alternative B2M.*

Closing the eastbound HOV off-ramp at the I-90 and Bellevue Way SE interchange is a design option for all Segment B alternatives, while closing the westbound HOV on-ramp is a design option for only Alternative B1. The potential closure of the HOV direct-access ramps would not affect bus services because the project would eliminate buses currently using these ramps; the exception, however, is Alternative B7, for which one bus route would be rerouted to the general-purpose ramp if the eastbound HOV direct-access off-ramp were to be closed.

Segment C

With light rail, there would be more direct transit connections between Downtown Bellevue and the areas served by East Link. In both the No Build Alternative and build alternatives, a Metro RapidRide route would connect downtown Bellevue, Overlake, and Redmond.

Preferred 108th NE At-Grade Alternative (C11A)

Under *Preferred Alternative C11A*, routes ST 550 and ST 556 would be eliminated. Other bus routes, such as ST 555 and ST 564/565, would be truncated to end at the Bellevue Transit Center and reduce redundancy with light rail service. All other modifications to the future transit service coverage and circulation for the Segment C area would be similar under the no-build and build conditions.

Preferred 110th NE Tunnel Alternative (C9T)

Under *Preferred Alternative C9T*, transit service coverage and circulation would be similar to the *Preferred Alternative C11A.*

Other Segment C Alternatives

Under the Couplet Alternative (C4A), transit that travels on 108th Avenue NE and 110th Avenue NE might need to be revised depending on the direction of the one-way vehicle couplet. All other modifications to the future transit service coverage and circulation under the Alternative C4A would be similar to the *Preferred Alternative C11A*.

For all other Segment C alternatives, bus service and circulation would be similar to the *Preferred Alternative C11A*.

Segment D

Without the East Link Project, there would be no direct transit connection between Bel-Red and Downtown Redmond because the bus routes connecting these areas would be deleted or modified. East Link would provide a direct connection between these areas. In addition, light rail would directly connect Bel-Red and Overlake to the South Bellevue, Mercer Island, University District, and Northgate areas. Light rail would also directly connect the Bel-Red area to Downtown Seattle.

Preferred NE 16th At-Grade Alternative (D2A)

Under the *Preferred Alternative D2A*, to serve the 120th Station, some bus routes' circulation patterns would be modified to use 120th Avenue NE instead of 116th Avenue NE between NE Bel-Red Road and NE 20th Street. Some services between the Bellevue Transit Center and the Overlake Transit Center would be reduced or eliminated if light rail extended to the Overlake Transit Center. If light rail terminated at Overlake Village Station, then some bus routes would be changed to serve that station. All other modifications to the future transit service coverage and circulation for the Segment D area would be similar under the no-build and build conditions.

Other Segment D Alternatives

For all other Segment D alternatives, transit service coverage and circulation would be similar to the *Preferred Alternative D2A*, except for Alternative D5, which does not have a 120th Station and, therefore, would not have any of the bus route modifications associated with that station.

Segment E

Under the No Build Alternative, there would be no direct transit connection between the downtown Redmond and Bel-Red areas. With light rail, new direct transit connections would be established between Downtown Redmond and the Bel-Red, South Bellevue, Mercer Island, and Northgate areas.

Preferred Marymoor Alternative (E2)

Under *Preferred Alternative E2*, the SE Redmond Station would be added, which would change transit service. Some bus routes would be revised to serve the SE Redmond Station, and these buses would use NE Redmond Way and NE 70th Street to access the SE Redmond Station. Some bus routes would continue using the Bear Creek Park-and-Ride as they would in the no-build condition. It was assumed that similar transit services would be provided at either the Redmond Transit Center or Downtown Redmond Station because they are both located in Downtown Redmond. All other modifications to the future transit service coverage and circulation for the Segment E area would be similar under the no-build and build conditions.

Other Segment E Alternatives

For all other Segment E alternatives, transit service coverage and circulation would be similar to the *Preferred Alternative E2*.

3.4.3.2 Transit Level of Service and Operations

Future transit hours of service and frequency would change with or without East Link to meet future transit needs. With the project, Metro and Sound Transit bus routes would be modified to develop an integrated transit network with transit hubs at many East Link stations. Some routes would be reduced or eliminated where bus service duplicates light rail service. Other routes would be modified to end at light rail stations. Some would be modified to stop at the new stations and continue. It was assumed that future Community Transit service in the area would be unaffected.

The following subsections show results for each of the measures used to evaluate transit LOS performance**.** Table 3-5 provides LOS values and associated grades for each of the transit LOS measures. Appendices B and C in the *Transportation Technical Report* provide more information on the LOS values and descriptions.

Service Frequency Level of Service

With the No Build Alternative, some areas would be connected by frequent service; however, many other areas would not have direct transit connections. Service frequency in the reverse-peak direction (eastbound in the morning [AM] and westbound in the afternoon [PM]) between Overlake and Downtown Seattle, and between Downtown Redmond and Downtown Seattle, would improve from the existing LOS C to LOS A. This service frequency improvement would be a result of planned more frequent headways of ST Route 545. Between Downtown Seattle and Downtown Bellevue, the service frequency would remain at a LOS B or better. With a few exceptions, the University District, Northgate, Mercer Island, South Bellevue, Bel-Red, Overlake and Downtown Redmond areas would not have direct bus service between them.

TABLE 3-5
Transit LOS Definitions

LOS	Service Frequency (minutes between arrivals)	Service Hours (in a day)	Passenger Load		Reliability (percent on-time)[a]
			Buses (passengers per seat)	Light Rail (square feet per standing passenger)	
A	Less than10	19 to 24	0.00 to 0.50	More than10.8[b]	95.0 to 100
B	10 to 14	17 to 18	0.51 to 0.75	8.2 to 10.8	90.0 to 94.9
C	15 to 20	14 to 16	0.76 to 1.00	5.5 to 8.1	85.0 to 89.9
D	21 to 30	12 to 13	1.01 to 1.25	3.9 to 5.4	80.0 to 84.9
E	31 to 60	4 to 11	1.26 to 1.50	2.2 to 3.8	75.0 to 79.9
F	More than 60	0 to 3	More than 1.5	Less than 2.2	Less than 75.0

Source: Transit Capacity and Quality Service Manual, Transportation Research Board (TRB), 2003.

[a] "On time" is 0 to 5 minutes late; early departures are not considered on time.

[b] This includes the potential for some cars to have no standing passengers.

Planned modification of some routes (elimination, truncation, and rerouting) would also decrease the service frequency LOS with some of the connections to and from the Bel-Red area. Service frequency would improve from LOS D to LOS C between the Downtown Bellevue and University District areas because headways would improve from 25 minutes to 15 minutes. Even though many of the bus routes are planned for more frequent headways, buses would likely be unable to meet their scheduled headways in the future due to additional congestion on roadways.

In both years 2020 and 2030, East Link would connect all of the areas with more frequent service. East Link trains would have a peak-period headway of up to 7 minutes (in year 2030) resulting in LOS A. The Eastside areas would be directly connected with light rail service, with frequent direct connections with the Bel-Red, Overlake, and Downtown Redmond areas. The chart on the left in Exhibit 3-7 shows the service frequency LOS for the No Build Alternative, and the chart on the right shows the service frequency LOS with the project during the PM peak period. Because the transit integration plan did not alter the transit service frequencies enough to shift the LOS between years 2020 and 2030 conditions, this exhibit analyzes both years.

Hours of Service Level of Service

With the No Build Alternative, in both years 2020 and 2030, the hours of service for direct bus service between most areas would be similar to the existing

conditions. Service between Downtown Seattle and Downtown Redmond would continue to operate over 19 hours per day (LOS A). All connections with the Bel-Red area would operate at LOS C or worse. With a few exceptions, the University District, Northgate, Mercer Island, South Bellevue, Bel-Red, Overlake and Downtown Redmond areas would not have direct bus service between them. The connection between Downtown Bellevue and Northgate would continue to operate at hours of service LOS E (11 hours or less) or worse.

With the East Link Project, the hours of service would be LOS A between all areas directly connected by light rail. East Link would either introduce new direct connections among them or would substantially improve existing service areas. East Link would operate for 20 hours each day, which would be a longer operating duration than a majority of the future bus routes. The Eastside areas would be directly connected with light rail service, with most noticeable hours of service improvements in the connections with Bel-Red, Overlake, and Downtown Redmond. Downtown Seattle to Downtown Bellevue, and Downtown Seattle to Downtown Redmond, would continue to have hours of service LOS A. Northgate and the University District, with light rail, would have direct connections with Mercer Island and all the Eastside areas (South Bellevue, Downtown Bellevue, Bel-Red, Overlake, and Downtown Redmond).

The chart on the left in Exhibit 3-8 shows the hours of service LOS without the East Link Project, and the chart on the right shows the hours of service LOS with the project. Because the transit integration plan did not alter the hours of transit service enough to shift the LOS between years 2020 and 2030 conditions, this exhibit analyzes both years.

Passenger Load Level of Service

The future passenger load LOS was calculated differently for buses and light rail per the *Transit Capacity and Quality of Service Manual* (Transit Cooperative Research Program, 2003). Because buses are intended to provide mostly seated transit service, the number of available seats was compared with the forecasted number of passengers. A ratio of more than one passenger per seat would mean that some passengers must stand. Light rail, however, is intended to provide both seated and standing service. When the number of passengers exceeds the number of available seats, some passengers must stand. Passenger load for light rail was calculated as the square footage available per standing passenger. As the available square footage decreases, the LOS degrades.

Compared with existing conditions, the number of transit passengers in the No Build Alternative in both 2020 and 2030 years would increase. Overall, the passenger load LOS with the No Build Alternative would be expected to operate at LOS C or better. A greater number of passengers per bus would occur at Screenlines 1 (Seattle) and 2 (Lake Washington). Across Screenline 2, the passenger load for Seattle-to-Bellevue bus routes would be LOS D, indicating all bus seats are used by passengers. Although the total number of transit passengers across the other screenlines would increase in the future No Build

EXHIBIT 3-8
2020 and 2030 Hours of Service LOS

Alternative, depending on the bus service modifications, the passenger load LOS would increase or decrease compared with existing conditions.

With East Link, the light rail 2020 passenger load LOS would be expected to operate at LOS A. Transit use would continue to increase in 2030 with light rail as more people choose to travel on light rail because of its frequency and reliability. By 2030, light rail passenger load operations are expected to be LOS A and B. With East Link, the number of passengers per bus would decrease and the bus passenger load LOS would be LOS A in both 2020 and 2030. The improvement to LOS A for buses with the project would be notable at Screenline 2, where the bus passenger load without the project in the year 2030 would operate at LOS C in both directions. While the passenger load LOS would improve with light rail, the number of transit (bus and light rail combined) riders would increase by about 25 percent across the lake compared with the No Build Alternative.

In the future, if the light rail passenger load LOS becomes unacceptable, the transit service provider might consider increasing service frequency or train length to improve the passenger load LOS and passenger comfort. In Segment A, if in the future the D2 Roadway did not operate as joint use for bus and light rail, the buses that use the D2 Roadway would be rerouted to other roadways such as SR 519 to access Downtown Seattle. This rerouting would slightly increase bus travel time, which could potentially affect bus passenger load. Screenline passenger load LOS levels are presented in Table 3-6.

Transit Reliability Level of Service

Future on-time performance and reliability LOS in the no-build and build conditions were analyzed using data from existing conditions because deviations from future headways cannot be predicted. It was assumed that in the future both Metro and Sound Transit would adjust their bus services according to the demand and congestion levels to maintain existing reliability, although unforeseen conditions could limit what would be implemented.

Bus Reliability

In the future both with and without East Link, the majority of bus routes at each of the five stations (International District/Chinatown, Mercer Island, Bellevue Transit Center, Overlake Transit Center, and Redmond Transit Center) are expected to operate with a reliability of LOS E or F. None of the 23 bus routes at either the International District/Chinatown or Mercer Island stations are expected to have a reliability better than LOS E. Only 3 out of the 18 evaluated routes at the Bellevue Transit Center would operate better than LOS E. Sound Transit Route 550, a key transit route in the study area that follows a route similar to that of the light rail alternatives between Seattle and Downtown Bellevue, would operate at LOS F in both directions at the Mercer Island Park-and-Ride Lot, which indicates that this route would almost always be off schedule and would have about a 50 percent probability of arriving on time. Only at the Overlake Transit Center and Redmond Transit Center would some bus routes operate with a reliability better than LOS D.

N/A Not applicable because light rail would not cross this screenline.

The continuation of poor reliability between Downtown Seattle and Downtown Bellevue would be expected because bus speeds between these two major urban centers are predicted to decrease slightly more than 30 percent by year 2030, even with improvements to I-90. This would occur because roadways connecting I-90 to these urban centers, especially to and from Bellevue, are not planned for improvements; therefore, congestion would worsen. Bus reliability LOS is presented in Table 3-7. While the bus reliability presented in Table 3-7 is based on existing data, future bus performance is expected to operate similar to or worse than existing conditions.

TABLE 3-7
Transit Reliability Level of Service at Stations

Station	Existing Bus		Future Light Rail[a] Level of Service[b]
	Percent On-Time Performance	Level of Service[b]	
International District/ Chinatown	48.8	F/E	A
Mercer Island	52.2	F/F	A
Bellevue Transit Center	53.3	F/E	A
Overlake Transit Center	52.4	F/C	A
Redmond Transit Center	45.3	F/D	A

[a] Light rail reliability performance was projected using St. Louis light rail data.

[b] LOS values are station averages; existing bus average LOS X/Y, where X=LOS for percent on-time performance station average, Y=LOS for coefficient of variation station average (definitions provided in the *Transportation Technical Report* [Appendix H1]).

Note: While the data used in this analysis were gathered during Downtown Seattle Transit Tunnel closure, data collected before the tunnel closure showed similar reliabilities (i.e., LOS E/F).

In Segment A, with light rail using the center roadway, buses would use the HOV lanes in the outer roadway during both construction and light rail operation. If performance of these HOV lanes is degraded, buses would likely not be able to maintain acceptable reliability because they would be operating in congested conditions in these HOV lanes.

If light rail and buses jointly use the D2 Roadway in Seattle, buses would gain up to a 2-minute savings inbound in the AM peak period to Downtown Seattle and up to a 6-minute savings outbound in the PM peak period from Downtown Seattle on I-90 compared to the operational option where buses would not be eligible to use the D2 Roadway. However, some of the savings would be reduced when buses travel along 5th Avenue South to and from the D2 Roadway. It would take up to 2 additional minutes to travel along 5th Avenue South compared to 4th Avenue South. Additionally, depending on the joint-use operating policy of the D2 Roadway, up to 3 additional minutes of average delay, in either direction, could be incurred by buses while waiting for clearance to enter the D2 Roadway. However, during evening events at the stadiums, bus routes along 4th Avenue South would incur additional travel time due to increased congestion along this street.

With an interim terminus station at the Ashwood/Hospital or Hospital station in Bellevue, current bus service would continue to serve the Bel-Red and Overlake areas with poor reliability. With an interim terminus farther east, the transit reliability in the Bel-Red and Overlake areas would improve with the direct service provided by light rail.

Light Rail Reliability

The poor bus reliability discussed above indicates that buses would be unable to meet their scheduled arrival times and would frequently arrive close together rather than at the desired intervals due to highly congested local and regional roadways. Poor reliability can make buses an unattractive mode for potential users and would be a major deterrent to transit use. Light rail would not experience the same disruptions in transit reliability as buses because light rail would operate in its own dedicated right-of-way, separate from vehicle congestion, and therefore would be able to accommodate higher ridership through more frequent and reliable service. In most cases, at-grade light rail routes would have priority at traffic signals.

The Puget Sound region's light rail system (Central Link) is in its first years of operation. The 2010 third quarter year-to-date service reliability indicates that the year-to-date adherence to schedule is around 80 percent, and the headway adherence is above 90 percent (Sound Transit, 2010). Refer to Appendix H1, *Transportation Technical Report*, of this Final EIS for information on how these percentages are calculated. Because the Puget Sound region's light rail system has different characteristics than assumed with the East Link Project (for example, current joint bus and rail operations in the Downtown Seattle Transit Tunnel are not assumed during East Link operations), and because Central Link is continuing to adjust operations to improve its reliability, East Link's expected reliability was estimated using the St. Louis light rail system's on-time performance data. St. Louis light rail includes features similar to East Link (such as at-grade crossings and tunnels) and is reported to be 93 percent on time. Other U.S. light rail lines report between 92 and 98 percent on-time performance. The *Transportation Technical Report* contains additional St. Louis light rail data. The estimated light rail reliability LOS for future conditions is presented in Table 3-7.

3.4.3.3 Transit Travel Time Savings

Door-to-door (from the beginning to the end of your trip—for example, when you leave your place of work, ride transit, and then reach your destination, such as entering your home) travel time is a key factor in forecasting potential transit ridership. For some potential transit riders, especially riders who have other available travel options, the ability to provide a transit service that saves them time is an important factor in their decision-making process. Table 3-8 shows the average transit travel times for the No Build Alternative and East Link in the PM peak period in year 2030. The comparisons reflect an average person's door-to-door transit travel time using a particular station and include the following factors:

- Bicycle or walk time to stop or station
- Wait time
- Transfer wait time(s), if any
- In-vehicle time (in bus and/or light rail)
- Drive, bicycle, or walk time to destination

Compared with the No Build Alternative, East Link patrons in the representative alternative would save between 4 and 16 minutes during the PM peak period in year 2030. While the values presented in Table 3-8 represent a travel time for any transit rider in the region connecting to transit at the East Link stations, transit riders making trips where their origin and destination areas are both served by East Link would have the greatest travel-time benefits. This is due to shorter waits, no transfer times, and high in-vehicle speeds. Travel time savings would be similar in years 2020 and 2030 with East Link.

An important component of the overall transit travel time is the actual time for a train to travel between stations. With the East Link Project, a passenger's travel time between Downtown Seattle and Downtown Redmond, after boarding light rail, would be between 29 and 39 minutes. Light rail travel time between Downtown Seattle and Downtown Bellevue would be less than 20 minutes. This would be a savings of about 25 minutes compared with an automobile currently traveling between these locations, as in the afternoon peak period it now takes up to 45 minutes to travel between Seattle and Bellevue (via I-90) and up to 55 minutes to travel between Seattle and Redmond (via SR 520) (WSDOT, 2011).

TABLE 3-8

Weighted average (all stations)	**60**	**51**	**61**	**52**

[a] Door-to-door means from the beginning to the end of your trip, for instance from when you leave your place of work to when you enter your home.

[b] Travel times for these stations were derived from their alternative, which is not included in the representative alternative combination. These alternatives are Alternative B1 (connecting with Alternative C1T), Alternative B7, *Preferred Alternatives C11A* and *C9T*, and E2 - Redmond Transit Center Design Option.

In the future these automobile travel times are expected to continue to get even longer, and therefore light rail would provide an even greater travel time savings. Exhibit 3-9 shows light rail travel times between key stations.

3.4.3.4 Transfers

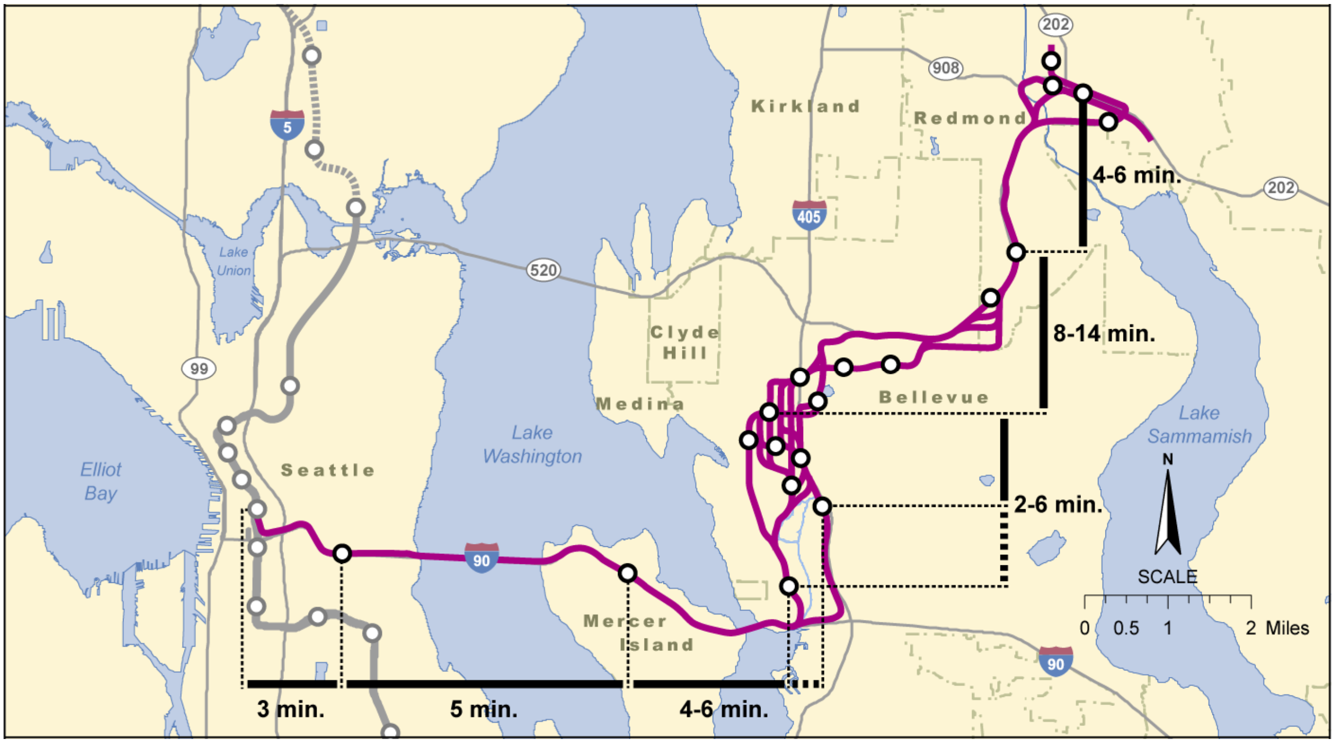
When transit riders are required to transfer, it is often perceived as a negative attribute of transit systems and an impediment to transit use. However, it is recognized that the quality of transfers, whether between buses or between bus and rail, has a dramatic impact on how negatively transfers are perceived. Factors determining quality of transfers include proximity of transfer location, wait time, waiting area conditions, and service reliability.

A slight reduction in transfer rate would be predicted with East Link because it would connect to the planned North Link light rail line and provide a one-seat transit trip between North Seattle and the Eastside.

Passengers transferring from bus to light rail would have shorter wait times compared with bus-to-bus transfers because the East Link operating plan assumes light rail trains in the peak periods would arrive every 8 minutes in 2020 and every 7 minutes in 2030. Even during off-peak hours, East Link would operate with 12-minute headways in 2020 and 10-minute headways in 2030. Because of the high reliability of light rail service, riders might choose a light rail trip that would result in a shorter wait time for transfers than a longer and potentially less reliable bus-only trip.

3.4.3.5 Station Parking

With the No Build Alternative, no expansion or changes would occur in existing park-and-ride capacities in the study area. With East Link, parking provided at the Mercer Island, Overlake Village, and Redmond Transit Center stations would remain unchanged. Depending on the alternative, new park-and-ride lots would be constructed at the 130th Station or 120th Station (proposed 300 stalls) with *Preferred Alternative D2A* and SE Redmond Station (proposed 1,400 stalls) and existing park-and-ride lots proposed to be expanded include the South Bellevue Station (approximately 1,400 additional stalls), 118th Station (proposed 1,030 stalls), and Overlake Transit Center Station (proposed 320 stalls) to better accommodate the expected ridership. Section 3.6 provides further details on parking and parking utilization at East Link stations.



Note: Estimated East Link travel time between the Mercer Island Station and the South Bellevue Station is about 4 minutes (solid line), between the Mercer Island Station and the 118th Station it is about 6 minutes (solid plus dashed line), between the South Bellevue Station and Bellevue Transit Center it is between 4 and 6 minutes (solid plus dashed line), and between the 118th Station and the Bellevue Transit Center it is about 2 to 4 minutes (solid line).

EXHIBIT 3-9
East Link Travel Times between Key Stations

3.4.3.6 Light Rail Ridership

The Sound Transit ridership forecasting model was used to develop the 2020 and 2030 light rail system ridership forecasts for each of the project alternatives.

The ridership forecasts use 2020 and 2030 land use forecasts based on the PSRC projections developed in 2005 and released in spring 2006. The transit ridership model also accounts for the voter-approved ST2 program and recent changes to background project schedules. The ridership forecasts and analysis also include the City of Bellevue's adopted Bel-Red Subarea Plan and the City of Redmond's Overlake Village Plan Update.

The segment ridership for each project alternative is the sum of the daily boardings at the stations in that alternative. Because the route, profile, and station locations vary for each alternative, changes are expected not only in the station boardings but also in the segment and projectwide ridership. The projectwide ridership is the total number of daily riders that would use East Link.

Daily ridership differences would be considered substantial if the forecasted variation among alternatives for total East Link ridership exceeded about 2,000 daily boardings. Generally, the variation among segment alternatives is expected to be less than 2,000 daily boardings because many of the segments include similar numbers of stations and the travel times are not different enough to cause a dramatic change in patronage. Station mode of access is discussed in Section 3.6. Ridership analysis methodology and results are presented in detail in Appendix H1, *Transportation Technical Report*, of this Final EIS.

Projectwide Ridership Summary

Based on the segment ridership forecasts discussed in the following sections, the full-length East Link Project would generate up to 45,000 riders in 2020 and up to 52,500 in 2030. There are several reasons for the variation in ridership among the alternatives. Alternatives C1T and C3T would generate the highest ridership among Segment C alternatives by connecting the commercial, retail, and office core of Downtown Bellevue through tunnel profiles that provide a relatively fast travel time. *Preferred Alternatives C11A* and *C9T* would generate ridership forecasts near the middle to lower end of the Segment C alternatives. Alternative B7, which generates the lowest projectwide ridership among Segment B alternatives, travels along a former BNSF Railway/I-405 route that would not stop at the South Bellevue Park-and-Ride. Alternative C14E would also generate a low projectwide ridership because it does not enter into the business and retail core of Downtown Bellevue as much as the other Segment C alternatives and, therefore, requires a longer walk to access the station. *Preferred Alternative D2A* would generate the highest ridership among Segment D alternatives. Exhibit 3-10 displays the 2030 projectwide ridership for each alternative by segment.

Preferred Alternative Ridership

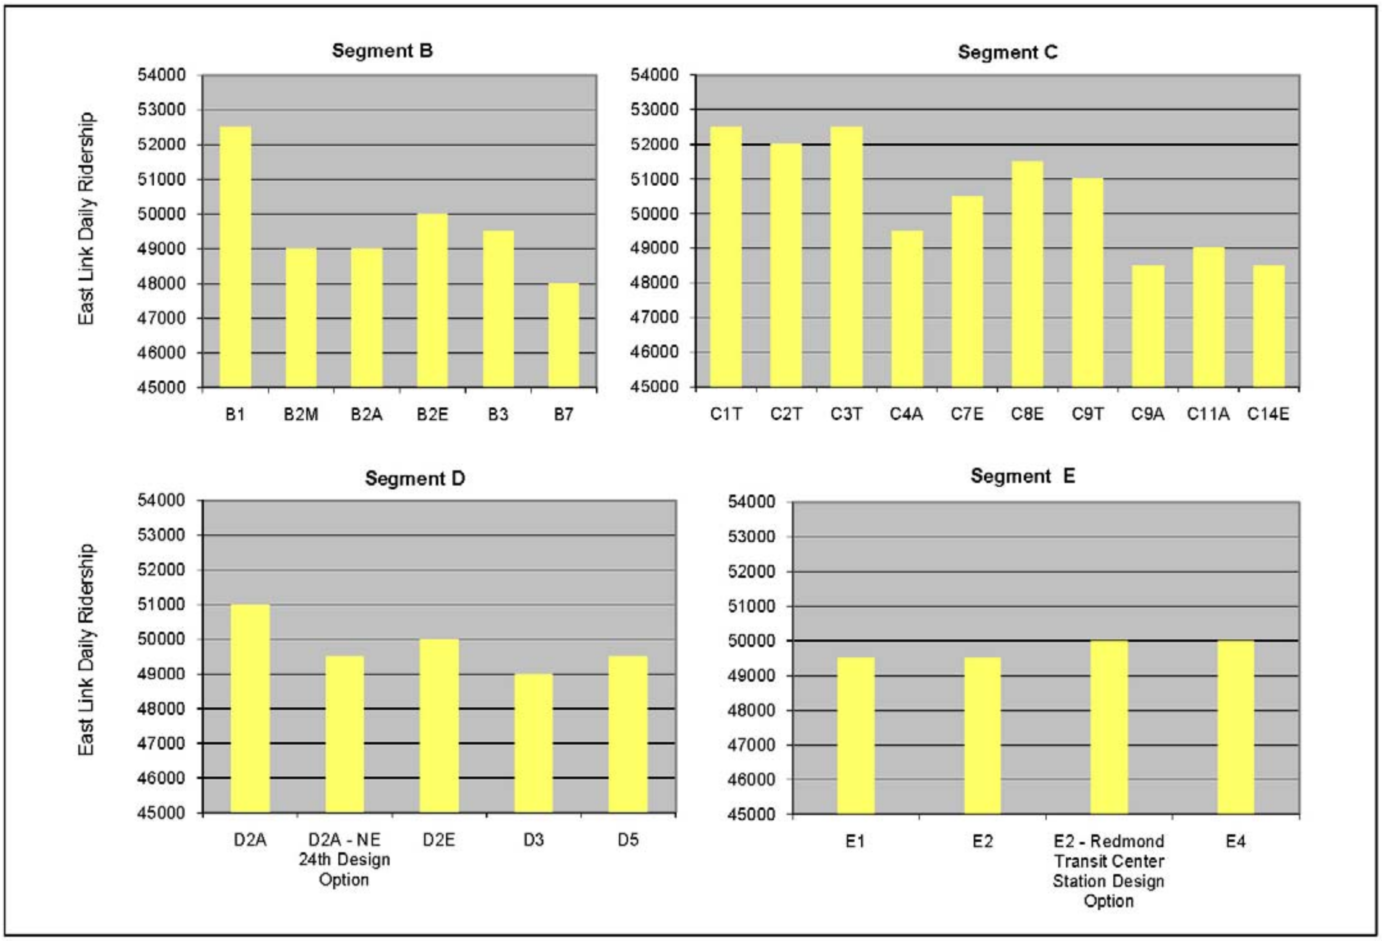
Table 3-9 lists the 2020 and 2030 projectwide ridership and boardings for the East Link *Preferred Alternative* (*Preferred Alternatives A1*, *B2M*, *C11A* and *C9T*, *D2A* and *E2*) in all five segments. The ridership forecasts presented in this table use a different approach from the forecasts that compare segment alternatives. Because the *Preferred Alternative* spans all five project segments, a "representative alternative" was not required to create a consistent ridership comparison for individual segments. For each year, two forecasts are provided in Table 3-9 because of the two preferred alternatives (*Preferred Alternatives C11A* and *C9T*) in Segment C.

Overall, projectwide ridership is very similar between the two preferred alternative forecasts, with 49,000 riders for *Preferred Alternative C11A* and 50,000 for *Preferred Alternative C9T*. The two alternatives would have very similar station and segment boardings within Segments A, D, and E. In Segment B, *Preferred Alternative C9T* would have 1,000 more boardings (5,500 compared with *Preferred Alternative C11A* with 4,500). The opposite is true for Segment C where *Preferred Alternative C11A* would have 1,000 more boardings than *Preferred Alternative C9T* (8,000 versus 7,000). One reason for the boarding differences between these two segments is the station locations. *Preferred Alternative C11A* has a 108th Station in Segment C and *Preferred Alternative C9T* has a SE 8th Station in Segment B.

Although not included in these ridership results, ridership between the Eastside and Seattle would be expected to be higher on days with special events at Safeco Field, Qwest Field, or other venues near the light rail system (e.g., for concerts, trade shows, other sporting events). East Link ridership would be anticipated to increase more than 8 percent on days with special events.

Alternative Ridership Forecasts by Segment

To forecast ridership for each alternative, a representative alternative was created to provide a baseline for the East Link Project. This representative alternative generally follows a combination of the *Preferred Interstate 90 Alternative (A1)*, 112th SE Bypass Alternative (B3), Couplet Alternative (C4A), NE 16th At-Grade Alternative (D2A) NE 24th Design Option,



Note: In Segment A, *Preferred Alternative A1* is forecasted to have a 2030 daily projectwide ridership of 49,500.

EXHIBIT 3-10
2030 Projectwide Daily Ridership

and the *Preferred Marymoor Alternative (E2)*. To assess each of the alternatives within a segment, the alternatives outside that segment being analyzed reflected the representative alternative, and, within the segment, each alternative was coded and ridership forecasts were prepared. This method provides a common baseline to compare the alternatives within each of the segments. Tables 3-10 through 3-14 provide the alternative ridership forecasts by segment. Included in these tables is a forecast for the preferred alternative for that segment. These forecasts, as described in this paragraph, are defined differently than the forecasts presented in Table 3-9. Refer to Appendix H1, *Transportation Technical Report*, of this Final EIS for further information on the methodology to forecast ridership for segment alternatives.

Segment A, *Preferred Interstate 90 Alternative (A1)* and Projectwide Ridership

Although there is only one project alternative in Segment A (the *Preferred Alternative I-90 [A1]*), the adjacent Segment B alternatives would affect its daily boardings because of the Segment B station's proximity to Segment A. The Segment A ridership forecasts are similar for all the Segment B alternatives except one because of a proposed station at the South Bellevue Park-and-Ride. Alternative B7 would have a station at 118th Avenue NE, not at South Bellevue, and it would cause a shift in travel patterns of the light rail users to the surrounding stations. Projectwide ridership would be about 40,000 riders in 2020 and up to 49,500 riders in 2030. The daily boardings at the Mercer Island Station in Segment A are expected to increase by around 1,000 under Alternative B7 in 2020 and 1,500 in 2030. Although this boarding information suggests a potential increase in the number of riders at the Mercer Island Station, the park-and-ride lot can only accommodate 447 vehicles; therefore, potential park-and-ride light rail riders exceeding this parking capacity would either use another station or alter their mode of transportation to access the station. Table 3-10 lists the projected 2020 and 2030 daily station boardings for Segment A.

TABLE 3-9
Year 2020 and 2030 Daily Ridership Forecasts for the Preferred Alternatives

Station	***2020***		***2030***

Projectwide Ridership	***39,500***	***40,500***	***49,000***	***50,000***

- = Station not included in alternative.

Note: Due to rounding, station ridership may not sum exactly to segment totals.

[a] A low level of transit signal priority is assumed to ensure key east-west arterials in Downtown Bellevue are not affected. This assumption is consistent with the traffic analysis presented in this chapter.

If the D2 Roadway that connects I-90 and the Downtown Seattle Transit Tunnel operated with exclusive light rail service, transit (bus and rail) ridership along I-90 in the peak periods would not noticeably change because a slight increase in rail ridership would be offset by a slight decrease in bus ridership.

Segment B Alternative and Projectwide Ridership

Table 3-11 lists the projected 2020 and 2030 Segment B alternative and station daily boardings.

Preferred 112th SE Modified Alternative (B2M)

In Segment B, projectwide ridership for *Preferred Alternative B2M* would be in the middle of the range in 2020 and 2030 with 39,500 and 49,000 riders, respectively. In terms of segment boardings, *Preferred Alternative B2M* would have similar ridership as the other Segment B alternatives, other than Alternative B7, with 4,500 in 2020 and 5,000 in 2030.

TABLE 3-10
Year 2020 and 2030 Daily Ridership Forecast in Segment A

Station	2020		2030	
	A1	***A1* (combined with B7)**	***A1***	***A1* (combined with B7)**
Rainier	3,000	3,000	3,000	3,000
Mercer Island	1,500	2,500	1,500	3,000
Segment A totals	**4,500**	**5,500**	**5,000**	**6,000**
Projectwide ridership	**40,000**	**39,000**	**49,500**	**48,000**

Note: Due to rounding, station ridership might not sum exactly to segment totals.

The reason the ridership varies between Alternatives B2M and B7 is because the locations and numbers of Segment B stations by alternative are different. With Alternative B7, riders may choose to access East Link in another segment (such as Segments A or C) due to the relative ease of accessing those stations rather than the stations in Segment B. This is reflected in the East Link project-wide ridership, which varies less between these alternatives compared to the segment boarding forecasts because riders are choosing to access East Link in a different segment.

Other Segment B Alternatives

Alternative B1 connecting with Alternative C1T would generate the highest projectwide daily ridership among Segment B alternatives: 42,500 riders in year 2020 and 52,500 riders in year 2030. Alternative B7 would generate the lowest projectwide daily ridership among Segment B alternatives with 39,000 riders in 2020 and 48,000 in 2030. The Old Bellevue Station, immediately north of the Segment B boundary, would contribute to the higher projectwide ridership for Alternative B1 because it is surrounded by a high concentration of medium- to high-density, mixed-use neighborhoods and it is close to commercial, retail, and office properties.

In year 2020, Segment B ridership for each alternative would range from a low of 1,500 daily boardings under Alternative B7 to a high of 4,500 daily boardings generated by *Preferred Alternative B2M* and Alternatives B2E and B2A. By 2030, ridership in Segment B would range from a low of 1,500 daily boardings with Alternative B7 to a high of 5,000 daily boardings with the *Preferred Alternative B2M* and Alternatives B2A and B2E.

The South Bellevue Station ridership would be similar for all alternatives that include this station. The year 2020 daily boardings at this station would be 4,000. In year 2030, this station would generate 4,500 daily boardings. In both years 2020 and 2030, the SE 8th Station would generate 500 daily boardings for all alternatives with this station. Alternative B7 would be the only route that would stop at the 118th Station, which would produce 1,500 daily boardings in both years 2020 and 2030. Boardings at the 118th Station are lower than at the South Bellevue Station because it would have less convenient auto and transit access with I-90.

Alternatives B3 and B7 also have an East Main Station in Segment C just north of the Segment B boundary. Under Alternative B3, this station is expected to generate 2,000 and 2,500 daily boardings in years 2020 and 2030, respectively, while under Alternative B7, the station would generate 2,500 and 3,000 daily boardings in these same forecast years, respectively.

TABLE 3-11
Year 2020 and 2030 Daily Ridership Forecast in Segment B

Station	2020						2030					
	B2M	**B1**	**B2E**	**B2A**	**B3[a]**	**B7**	***B2M***	**B1**	**B2E**	**B2A**	**B3[a]**	**B7**
South Bellevue	4,000	4,000	4,000	4,000	4,000	-	4,500	4,500	4,500	4,500	4,500	-
SE 8th	500	-	500	500	-	-	500	-	500	500	-	-
118th	-	-	-	-	-	1,500	-	-	-	-	-	1,500
Segment B totals	**4,500**	**4,000**	**4,500**	**4,500**	**4,000**	**1,500**	**5,000**	**4,500**	**5,000**	**5,000**	**4,500**	**1,500**
Projectwide ridership	**39,500**	**42,500**	**40,500**	**39,500**	**40,000**	**39,000**	**49,000**	**52,500**	**50,000**	**49,000**	**49,500**	**48,000**

[a] Alternative B3 and the B3 - 114th Extension Design Option would produce similar ridership forecasts.

- = Station not included in alternative.

Notes:
All Segment B alternatives are connected to Alternative C4A in Segment C to create a consistent ridership comparison except Alternative B1, which is connected to Alternative C1T. Due to rounding, station ridership might not sum exactly to segment totals.

Segment C Alternative and Projectwide Ridership

Tables 3-12 and 3-13 lists the projected 2020 and 2030 Segment C alternative and station daily boardings with a connection to Alternatives B3 and B7 and with a connection to *Preferred Alternative B2M* or Alternative B2A, respectively.

Preferred 108th NE At-Grade Alternative (C11A)

By year 2030, projectwide daily ridership for *Preferred Alternative C11A*, with a connection to Alternative B3, would be 49,000. This would be near the lower end of the range for Segment C alternatives. *Preferred Alternative C11A* would be the only Segment C alternative that provides the 108th Station, which would be in lieu of an East Main Station or a SE 8th Station. *Preferred Alternative C11A* is forecasted to be in the middle of the range for segment boardings with 6,500 in 2020 and 8,000 in 2030 with a connection to Alternative B3.

With a connection to Alternative B7, projectwide ridership decreases to 47,000, but segment boardings increase to 9,000 in year 2030 compared with Alternative B3. With a connection to *Preferred Alternative B2M* or Alternative B2A, projectwide ridership and segment boardings would remain similar to a connection with Alternative B3 due to a similar number of stations and location for these Segment B Alternatives.

Preferred 110th NE Tunnel Alternative (C9T)

By the year 2030, daily projectwide ridership for *Preferred Alternative C9T,* with a connection to Alternative B3, would be 51,000. This would be in the middle of the range for Segment C alternatives. *Preferred Alternative C9T* is forecasted to have 6,500 boardings in 2020 and 8,000 boardings in 2030 with this B3 connection. With a connection to Alternative B7, projectwide ridership would decrease to 49,000, but segment boardings increase to 9,000 in year 2030 compared to Alternative B3. With a connection to *Preferred Alternative B2M* or Alternative B2A, projectwide ridership, compared with Alternative B3, would decrease to 50,000 and segment boardings to 7,000. This is due to a change in the station locations as a SE 8th station is provided with *Preferred Alternative B2M* or Alternative B2A instead of an East Main Station with Alternative B3.

Other Segment C Alternatives

In 2020, the projectwide ridership under the Segment C alternatives would range from 39,000 to 43,000 with a connection to Alternative B3 and range from 37,000 to 41,500 with a connection to Alternative B7. By 2030, the projectwide ridership under the Segment C alternatives would range from 48,500 to 52,500 with a connection to Alternative B3 and range from 46,000 to 51,000 with a connection to Alternative B7.

With a connection to *Preferred Alternative B2M* or Alternative B2A, projectwide ridership for Segment C alternative would range from 39,000 to 42,500 in year 2020 and by year 2030 would range from 48,500 to 52,000. The following discussion of Segment C ridership assumes a connection to Alternative B3; refer to Tables 3-14 and 3-15 for the comparison with Alternative B7 and *Preferred Alternative B2M* and Alternative B2A, respectively. In general, with a connection to *Preferred Alternative B2M* or Alternative B2A, projectwide ridership would either remain similar or be slightly reduced compared with a connection with Alternative B3, but would be higher than with a connection to Alternative B7.

Alternatives C1T and C3T would result in the highest East Link projectwide ridership by connecting to the center of the commercial, retail, and office core of Downtown Bellevue and the Bellevue Transit Center. These alternatives are also expected to have shorter Segment C travel times because they would be inside a tunnel with a relatively direct route. The projectwide ridership under Alternatives C1T and C3T would be 52,500 daily boardings in year 2030.

In year 2020, Alternatives C9A and C14E would result in the lowest East Link ridership among the Segment C alternatives, with 39,000 daily riders. By year 2030, both of these alternatives would continue to have the lowest East Link ridership, 48,500 riders. Alternative C14E has a lower ridership compared to other Segment C alternatives because it would be located on the edge of downtown Bellevue.

In year 2020, total Segment C ridership for each alternative would range from a low of 4,500 daily boardings for the Alternative C14E to a high of 7,000 daily boardings for Alternatives C1T, C2T, and C3T. By 2030, Segment C total ridership would be expected to increase from a low of 5,500 daily boardings for Alternative C14E to a high of 9,000 daily boardings for Alternatives C1 and C3T. The Old Bellevue Station, which would be only included in Alternative C1T, would generate 1,500 and 2,500 daily boardings in years 2020 and 2030, respectively. The East Main Station would have ridership of 2,000 daily boardings in 2020 and 2,500 daily boardings in 2030. Ridership at the East Main Street Station Design Option under *Preferred Alternative C9T* would be similar to the East Main Station. The 108th Station, which would only be included in *Preferred Alternative C11A*, would generate 1,500 daily boardings in 2020 and 2,000 daily boardings in 2030.

TABLE 3-12
Year 2020 and 2030 Ridership Forecasts in Segment C (connecting from Alternative B3 or B7)

	2020										2030									
Station	***C11A*[a]**	***C9T***	**C1T**	**C2T**	**C3T**	**C4A[a]**	**C7E**	**C8E**	**C9A[a]**	**C14E**	***C11A*[a]**	***C9T***	**C1T**	**C2T**	**C3T**	**C4A[a]**	**C7E**	**C8E**	**C9A[a]**	**C14E**

Notes: Ridership forecasts outside the parentheses are when Segment C alternatives are connected to Alternative B3. Forecasts within the parentheses are when Segment C alternatives are connected to Alternative B7. The exception to this is Alternative C1T, which is connected to Alternative B1.

Due to rounding, station ridership might not sum exactly to segment totals.

[a] A low level of transit signal priority is assumed to ensure key east-west arterials in downtown Bellevue are not affected. This assumption is consistent with the traffic analysis presented in this report.

- Station not included in alternative.

TABLE 3-13
Year 2020 and 2030 Ridership Forecasts in Segment C (connecting from *Preferred Alternative B2M* or Alternative B2A)

Station	**2020**										**2030**									
	C11A[a]	***C9T***	**C1T**	**C2T**	**C3T**	**C4A**[a]	**C7E**	**C8E**	**C9A**[a]	**C14E**	***C11A***[a]	***C9T***	**C1T**	**C2T**	**C3T**	**C4A**[a]	**C7E**	**C8E**	**C9A**[a]	**C14E**

Note: Due to rounding, station ridership might not sum exactly to segment totals.

- Station not included in alternative

The Bellevue Transit Center Station would have a range of ridership between 3,500 and 5,000 daily boardings in 2020 and between 4,000 and 6,000 daily boardings in 2030. Alternative C1T would generate the highest daily boardings at the Bellevue Transit Center, with 5,000 daily boardings in 2020 and 6,000 in 2030. In contrast, Alternatives C7E, C9A, and C14E would generate the lowest daily boardings of 3,500, in year 2020. Alternative C7E would generate 3,500 daily boardings at the Bellevue Transit Center, the lowest daily boardings in 2030.

The Ashwood/Hospital Station is projected to generate 500 daily boardings in 2020 and 1,000 in 2030 for all alternatives. The Hospital Station would be expected to generate 500 daily boardings in 2020 for all alternatives except Alternative C14E, which would produce 1,000 in 2020. The same pattern would be expected in 2030 with 1,000 daily boardings for all alternatives except Alternative C14E, which would produce 1,500 daily boardings in 2030. This slight increase in boardings under Alternative C14E is due in part to decrease of accessibility at Bellevue Transit Center relative to the Hospital Station and slightly faster travel times because the alternative is located along the eastern edge of downtown Bellevue.

Segment D Alternative and Projectwide Ridership

Table 3-14 lists the projected 2020 and 2030 Segment D alternative and station daily boardings.

Preferred NE 16th At-Grade Alternative (D2A)
By year 2030, projectwide daily ridership for *Preferred Alternative D2A* would be 51,000, which would be the highest for Segment D alternatives. *Preferred Alternative D2A* would also have the highest segment boardings in both 2020 and 2030 with 5,500 and 7,000 boardings, respectively. This would be due in part to the alternative having a shorter route in this segment than most of the other Segment D alternatives while serving the key retail, commercial, and employment areas proposed as part of the Bel-Red Corridor Project EIS by the City of Bellevue. The D2A – 120th Station Design Option would be expected to have a similar ridership forecast as the *Preferred Alternative D2A*.

Other Segment D Alternatives
In year 2020, while the *Preferred Alternative D2A* would have the highest daily projectwide ridership with 41,500 in 2020, D2A - NE 24th Design Option and Alternatives D3 and D5 would result in the lowest daily ridership projectwide with 40,000 in 2020. In 2030, *Preferred Alternative D2A* would again result in the highest number of projectwide riders at 51,000, and Alternative D3 would result in the lowest projectwide ridership of 49,000. These differences do not constitute a substantial difference in ridership between the Segment D alternatives. In year 2020, ridership for Segment D alternatives would range from 4,500 to 5,500 daily boardings. By 2030, Segment D total ridership for Segment D alternatives would be expected to range from 6,000 to 7,000 daily boardings.

The 120th Station, which would be included in all alternatives except Alternative D5, would generate 500 daily boardings in year 2020. In 2030, daily boardings at the 120th Station would range between 500 and 1,000. The 130th Station, which is also included in all Segment D alternatives except Alternative D5, would generate 1,000 daily boardings in both years 2020 and 2030. If parking were provided at the 120th Station instead of the 130th Station, the station boarding forecasts would switch between the two stations.

The Overlake Village Station would have 1,000 daily boardings for all alternatives in year 2020 and between 1,000 and 1,500 daily boardings in 2030. *Preferred Alternative D2A*, D2A - NE 24th Design Option, and Alternative D3 are expected to generate 1,000 daily boardings at this station in 2030, whereas Alternatives D2E and D5 are expected to generate 1,500 daily boardings at this station.

In year 2020, Overlake Transit Center would be expected to generate 2,500 daily boardings for all alternatives except *Preferred Alternative D2A* and Alternative D5, for which they would generate 3,000 daily boardings. In year 2030, the daily boardings would range from a low of 3,500 with Alternatives D2A - NE 24th Design Option, D2E and D3 to a high of 4,500 under Alternative D5. Because only two stations would serve the Bel-Red and Overlake areas under Alternative D5, this alternative would generate slightly higher station ridership at the Overlake Village and Overlake Transit Center stations than the other alternatives. Nearby stations in adjacent segments also would have slightly higher ridership because Alternative D5 would require less travel time than the other alternatives. If a pedestrian/bicycle bridge were constructed connecting Overlake Transit Center Station to the properties west of SR 520, then transit ridership would be expected to increase at this station.

Although both the 120th and 130th Stations were analyzed for the *Preferred Alternative D2A,* D2A - NE 24th Design Option, and Alternatives D2E and D3, only one station may ultimately be constructed. If this were to occur, then ridership would not substantially change from what is presented in Table 3-14 because these stations' coverage areas overlap. Riders would likely consolidate to the one station.

Sound Transit's ridership model uses population and employment growth for future forecast years that have been adopted by the regional planning agency, PSRC. The future growth from the City of Bellevue and City of Redmond studies (Bel-Red Corridor Project EIS [City of Bellevue, 2007] and Overlake Neighborhood Plan [City of Redmond, 2007]) has yet to be fully adopted by the PSRC. However, these two studies are included in both cities' long-range development and economic goals. Therefore, growth in these areas was adjusted in these ridership forecasts with assistance from PSRC, the City of Bellevue, and the City of Redmond. Based on ridership forecasts included in the Bel-Red Corridor Project EIS [City of Bellevue, 2007], if the land uses surrounding the stations were developed to be oriented toward transit use, then the projected East Link ridership could be higher. Any increase in ridership caused by this type of development would be pedestrian or bicycle trips from the areas immediately surrounding the stations.

Segment E Alternative and Projectwide Ridership

Table 3-15 lists the projected 2020 and 2030 Segment E alternative and station daily boardings.

Preferred Marymoor Alternative (E2)
By year 2030, projectwide daily ridership for *Preferred Alternative E2* would be 49,500. *Preferred Alternative E2* would have segment boardings of 3,000 in 2020 and 3,500 in 2030.

Other Segment E Alternatives

All Segment E alternatives generate very similar daily projectwide ridership, varying by 500 in both 2020 and 2030. These differences do not constitute a substantial difference in ridership between the Segment E alternatives. In forecast year 2020, total Segment E ridership for all alternatives would be 3,000 daily boardings. By 2030, Segment E total ridership would be expected to increase to 3,500 and 4,000 daily boardings.

The SE Redmond Station would be expected to generate 1,500 daily boardings in 2020 and between 1,500 and 2,000 in 2030. The Redmond Town Center Station is expected to generate between 1,000 and 1,500 daily boardings in years 2020 and between 1,500 and 2,000 in 2030. The Downtown Redmond Station, which would only be included with *Preferred Alternative E2*, would be expected to generate 1,000 daily boardings in year 2020 and 1,500 daily boardings in year 2030.

Interim Terminus Ridership

The Hospital, Ashwood/Hospital, 120th, 130th, Overlake Village, Overlake Transit Center, SE Redmond, and the Redmond Town Center Stations could potentially serve as interim terminus stations although the East Link Project is funded to extend as far as the Overlake Transit Center. The Overlake Transit Center is therefore considered the most reasonable interim terminus. Table 3-16 compares the projected year 2020 and 2030 daily interim terminus station and projectwide ridership for each station as an interim terminus. The three interim terminus stations that would expect to have a noticeable increase in ridership are at the Hospital, Overlake Village and Overlake Transit Center Stations. By 2030, up to 3,000 daily riders are expected at the Hospital Station, up to 3,500 daily riders are expected at the Overlake Village Station, and up to 6,000 daily riders are expected at the Overlake Transit Center Station.

3.4.4 Construction Impacts

During construction of East Link, current bus routes would be affected at some locations along the corridor. Bus reliability could potentially degrade along arterials with construction for East Link due to lane closures and other construction-related activity. For areas with construction in the roadway right-of-way, arterials may be reduced to one lane in each direction, affecting roadway operations, including bus service along those arterials. In general, alternatives constructed outside the roadway right-of-way would have minimal impacts on bus routes.

3.4.4.1 Segment A, Preferred Interstate 90 Alternative (A1)

East Link construction impacts on Central Link operations would be minimal. Impacts would occur with the connection of East Link to Central Link in the Downtown Seattle Transit Tunnel. The Downtown Seattle Transit Tunnel construction activities would likely be scheduled to occur over a limited number of full weekend closures. Minor additional evening closures likely would be required for other technical work. When possible, the evening closures would be outside of revenue service hours. These construction impacts would be to Central Link service only because bus service would have previously shifted from the tunnel to surface streets.

Along I-90, construction would affect the bus routes stopping at Rainier Avenue S and at Mercer Island. Bus service would continue at these locations during the D2 Roadway construction but buses would use the outer I-90 mainline roadways to access the Rainier Avenue S and Mercer Island stops. During construction of light rail track on the D2 Roadway, buses would be rerouted to the I-90 mainline and use the HOV lanes completed as part of the I-90 Two-Way Transit and HOV Project. These HOV lanes would be completed before East Link is constructed on I-90.

3.4.4.2 Segment B

At the South Bellevue Park-and-Ride, the entire parking lot would be closed due to parking garage and station construction, but bus service and bus stops would remain on Bellevue Way SE.

For *Preferred Alternative B2M*, it is likely that less disruption would occur to transit service than Alternatives B1, B2A, B2E, B3, and the B3 - 114th Extension Design Option because only one lane of Bellevue Way SE would likely be closed for most of the civil construction period rather than multiple lanes. *Preferred Alternative B2M* and Alternatives B2A, B2E, and B3, and the B3 - 114th Extension Design Option would reconstruct a portion of the roadway on 112th Avenue SE. This construction would close lanes, thereby reducing the reliability of buses that travel along these roads during periods when lanes are closed. For Alternative B7, bus service at the Wilburton Park-and-Ride would continue, but all or some parking would be removed.

TABLE 3-16
Year 2020 and 2030 Daily Terminus Station and Projectwide Ridership Forecasts for Interim Terminus Stations

Year	Ridership Category	Full-Length Project[a]	Interim Terminus at: Ashwood/ Hospital	Hospital	120th	130th	Overlake Village	Overlake Transit Center	Redmond Town Center	SE Redmond
2020	Interim terminus station ridership[b]	N/A	1,000	2,000	1,000	1,000	2,500	4,500	2,000	2,000
	Projectwide ridership	40,000	31,000	27,000	30,500	31,500	32,500	37,500	39,500	39,000
2030	Interim terminus station ridership[b]	N/A	1,000	3,000	1,500	1,500	3,500	6,000	2,500	2,500
	Projectwide ridership	49,500	37,500	33,000	37,000	38,500	39,500	46,500	49,000	48,000

[a] Full-length project alternative is the combination of Alternatives A1, B3, C4A, D2A – NE 24th Design Option, and E2.

[b] Station and projectwide ridership might vary depending on which alternative connects to the terminus station.

Note: Due to rounding, station ridership might not total exactly to segment totals.

3.4.4.3 Segment C

Constructing *Preferred Alternatives C11A* and *C9T* would either consist of a full closure or a staged partial closure of the Bellevue Transit Center. In either scenario, impacted bus routes and stops would be rerouted along 106th, 108th, and 110th Avenues NE. Bus routes and stops might also be relocated to a nearby off-street location. One potential off-street location is on 108th Avenue NE, near NE 6th Street. This site would be able to accommodate some of the existing Bellevue Transit Center routes and stops.

For Alternatives C1T, C2T, and C3T, buses would not be able to access the transit center during construction. The Bellevue Transit Center would be closed for more than a year to construct the new station for these three alternatives; therefore, bus services and stops associated with these alternatives would be rerouted and relocated along 106th, 108th, and 110th Avenues NE.

The remaining Segment C alternatives likely would be able to retain current bus service within the Bellevue Transit Center during the construction period. Constructing the at-grade track along 108th Avenue NE (*Preferred Alternative C11A*) would affect bus routes along this road. Cut-and-cover construction on Bellevue Way (for Alternative C1T) between SE 6th and NE 6th Streets, on 106th Avenue NE (for Alternative C2T) between Main and NE 6th Streets, and on 110th Avenue NE (for *Preferred Alternative C9T*) would affect bus routes along these roadways. Alternative C4A would reconstruct 108th and 110th Avenues NE, which would affect bus service. The elevated construction of Alternative C8E and the at-grade construction of Alternative C9A would affect bus routes traveling on 110th Avenue NE. Construction activities surrounding NE 6th Street between 110th Avenue NE and the I-405 direct-access ramps (*Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C3T, C9A, and C14E) could affect bus routes. All of these potential construction impacts could increase bus travel times.

3.4.4.4 Segment D

During construction at the Overlake Transit Center Station, bus service and stops could be routed along 156th Avenue NE and/or other nearby arterials because the parking lot would be closed to construct the parking garage and station. For Alternative D3, buses traveling on 152nd Avenue NE, north of NE 24th Street, would be affected by the at-grade station construction in the median and also along NE 20th Street between 136th Avenue NE and 152nd Avenue NE, due to median trench construction. These impacts could increase bus travel times.

3.4.4.5 Segment E

Buses traveling along 161st Avenue NE between Cleveland Street (SR 202) and NE 87th Street would be affected by at-grade construction of E2 - Redmond Transit Center Design Option and would likely need to be rerouted. Under *Preferred Alternative E2*, which would terminate at the Downtown Redmond Station, and all other Segment E alternatives, potential impacts along 161st Avenue NE would be avoided.

3.4.5 Potential Mitigation

If the D2 Roadway is not designated for joint use operations with bus and light rail in the future, then bus routes that currently use the D2 Roadway would be expected to be rerouted to 4th Avenue South to access Downtown Seattle via SR 519. Transit signal priority could be implemented on 4th Avenue South at the I-90 western terminus and Airport Way South to improve bus reliability for these affected routes.

During East Link operations, bus routes on I-90 would not require any mitigation because the I-90 Two-Way Transit and HOV Project would be completed prior to East Link construction. This project would provide HOV lanes in both directions on I-90 between Mercer Island and the Rainier Avenue S interchange. Consistent with WSDOT's HOV Speed and Reliability Standard of a vehicle able to travel at least 45 miles per hour (mph) during the peak commuting hour 90 percent of the time, bus reliability would remain similar to that of the No Build Alternative.

No other transit mitigation during East Link operations would be required for the East Link Project because the project would have a beneficial impact on transit service. The transit integration plan provides coordinated bus service with the light rail system, and major park-and-ride lots in the study area would be expanded to better accommodate the increase in transit ridership with the project.

During construction, the existing South Bellevue (associated with all Segment B alternatives, except B7) and Overlake Transit Center (associated with all Segment D alternatives) park-and-ride lots would either be partially or fully closed. Measures to mitigate the loss of parking at these locations could include the following:

- Route transit riders that use these locations to available spaces at nearby park-and-ride lots, such as the Eastgate or Overlake Village Park-and-Rides.
- Lease parking lots and/or new parking areas within the vicinity of the closed park-and-ride lots.

During construction, transit service mitigation measures for the South Bellevue, Bellevue Transit Center (associated with *Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, and C3T) and Overlake Transit Center partial or full closure could include the following:

- Relocate transit stops to adjacent streets.
- Provide a temporary transit center at a nearby off-street location.
- Revise transit services. For example, at South Bellevue and Overlake Transit Center, bus routes that stop within the park-and-ride would be rerouted, to the extent possible, to on-street stops (for example along Bellevue Way SE and 156th Avenue NE) to ensure service during construction.

During construction of alternatives within street rights-of-way, buses would be rerouted to nearby arterials where appropriate to maintain transit service. For example in Downtown Bellevue, transit could be rerouted to parallel streets. In other areas, such as Bellevue Way SE, buses would continue to operate along this arterial due to lack of alternative routes.

Transit service modifications would be coordinated with King County Metro and private transit service providers to minimize construction impacts and disruptions to bus facilities and service. This could include posting informative signage before construction at existing transit stops that would be affected by construction activities. Refer to Section 3.5 for mitigation regarding future I-90 operations and Section 3.6 for mitigation regarding arterial and local street traffic operations.

3.5 Highway Operations and Safety

This section describes highway operations within the study area and the potential impacts on highways from the East Link Project. I-90 is the only regional highway that would be directly affected by the project; direct impacts on SR 520 and I-405 would be limited to light rail transit overpasses, parallel routes, and construction; therefore, operations on these two highways would be similar with or without the project.

For discussion of regional travel, including VMT, VHT, roadway v/c ratio, and mode choice at the six project screenline locations, refer to Section 3.3. For the analysis of intersection operations at or near I-90 ramp terminals refer to Section 3.6.

3.5.1 Methodology

Four key measures were established to evaluate the quality of operating conditions on I-90: vehicle and person throughput, travel time by transportation mode, LOS, and safety. Vehicle and person throughput is a measure of the number of vehicles and people who are able to cross a specific location. Person throughput is a more appropriate assessment measure than vehicle throughput for analysis of a transit project because it illustrates the overall efficiency of the system through number of people moved instead of vehicles. I-90 throughput information is presented at the Lake Washington Screenline (Screenline 2; see Exhibit 3-1) to explain changes in travel patterns across the lake, while the Mercer Slough Screenline (Screenline 3; see Exhibit 3-2) is intended to be used to understand I-90 conditions, east of the study area.

Travel times provide information on how long it would take to travel through the corridor or certain paths within the corridor. Congestion maps, which indicate roadway LOS, are charts that indicate when, how long, and how severe congestion would be on I-90. A safety comparison between the No Build Alternative and the East Link Project is provided to show how the project might affect the number of I-90 accidents. Appendix H1, *Transportation Technical Report*, of this Final EIS provides more details on the freeway operations analysis.

Vehicle Throughput. The number of vehicles that cross a location.

Person Throughput. The number of people in vehicles (autos and transit) who cross a location.

3.5.2 Affected Environment

Segment A is the only segment in which the East Link Project would directly affect a regional highway, I-90, during project operations. Potential impacts on SR 520, I-5, and I-405 from East Link Project operation are not considered to be substantial, as indicated in Section 3.3. Therefore, traffic operations on SR 520 (which also crosses Screenline 2) and I-5 and I-405 were not evaluated further. SR 520 is addressed in this section only when describing travel predictions across the lake in Section 3.5.2.2 and potential construction impacts (along with I-405) in Section 3.5.3.4.

Segment A spans approximately 7 miles, originating at the International District/Chinatown Station in Seattle and terminating where I-90 reaches South Bellevue. Within this segment that crosses Lake Washington, I-90 consists of two "outer" roadways that are the westbound and eastbound mainline lanes and a two-lane center roadway that has peak-directional reversible lanes that are for transit, HOVs, and Mercer Island residents driving between Seattle and Mercer Island, per the 1976 Memorandum of Agreement. Consistent with long-standing regional objectives of connecting the urban communities in the Puget Sound region, the center roadway has always been intended as an HCT connection between Bellevue and Seattle to support higher density employment and residential land uses on both sides of Lake Washington. This is documented in Appendix H of the *Transportation Technical Report* (Appendix H1), where a 2004 amendment to the 1976 I-90 Memorandum Agreement states "Alternative R-8A, with HCT deployed in the center lanes, is the ultimate configuration for I-90 in this segment."

3.5.2.1 Vehicle and Person Throughput

In existing conditions, slightly over 55 percent of the total number of vehicles on I-90 travel in the peak direction (westbound in the AM peak hour and eastbound in the PM peak hour). In the AM peak hour, slightly less than 13,000 vehicles travel on I-90, while in the PM peak hour, slightly over 13,500 vehicles travel on I-90. In both AM and PM peak hours, the center roadway accommodates less than 15 percent of the total vehicles on I-90 due to its limited access. Access is provided by ramps from the outer mainline roadways and the 5th Avenue South and South Dearborn Street intersection, neither of which provides enough capacity to effectively use the two lanes across Lake Washington in the reversible center roadway (WSDOT and Sound Transit, 2004, p 3-28). Table 3-17 lists I-90 vehicle throughput data for Screenlines 2 and 3 in the AM and PM peak hours.

TABLE 3-17
Existing (2007) I-90 AM and PM Peak-Hour Vehicles and Persons

Screenline/ Direction	AM Peak Hour				PM Peak Hour			
	Vehicles	Persons	Vehicle Percent of Total	Person Percent of Total	Vehicles	Persons	Vehicle Percent of Total	Person Percent of Total
Screenline 2 (Lake Washington)								
Westbound outer roadway	5,450	6,250	43	39	6,000	7,500	44	43
Reversible center roadway	1,750	3,350	14	21	1,850	3,450	14	20
Eastbound outer roadway	5,500	6,500	43	40	5,650	6,500	42	37
Screenline 2 Total	**12,700**	**16,100**	**100**	**100**	**13,500**	**17,450**	**100**	**100**
Screenline 3 (Mercer Slough)								
Westbound outer roadway	7,200	9,550	58	61	6,000	6,500	45	45
Eastbound outer roadway	5,300	6,000	42	39	7,250	7,950	55	55
Screenline 3 total	**12,500**	**15,550**	**100**	**100**	**13,250**	**14,450**	**100**	**100**

Source: Results from VISSIM software (CH2M HILL, 2007).

In terms of person throughput, in the AM peak hour on the Lake Washington Screenline (Screenline 2), the westbound outer roadway throughput approaches 6,300 persons. The reversible center roadway (westbound direction in the AM peak hour) person throughput is approximately 3,300 persons (of which about 25 percent are in buses). The eastbound throughput is about 6,500 persons. Overall, about 16,100 people travel I-90 in both directions during the AM peak hour.

In the PM peak hour on the I-90 floating bridges, the westbound throughput is about 7,500 persons. The eastbound outer roadway throughput is slightly over 6,500 persons, and the reversible center roadway (eastbound direction in PM peak hour) throughput is about 3,500 persons (of which about 20 percent are in buses). Overall, about 17,500 people travel I-90 in both directions during PM peak hour.

Similar person throughput trends occur at Screenline 3, except in the eastbound direction during the PM peak hour. Transit usage decreases compared to Screenline 2 because some passengers disembark at Mercer Island and some buses exit I-90 at Bellevue Way and therefore do not cross Screenline 3.
Exhibit 3-11 shows the existing AM and PM peak-hour person throughput by direction and mode at Screenlines 2 and 3. The person and vehicle throughput in the reversible center roadway is included in the direction it operates, depending on the time period.

3.5.2.2 Travel Time

Travel time paths between Seattle, Mercer Island, Bellevue Way, and I-405 were identified to help understand local and regional trip times. The selected travel paths are listed in Table 3-18 along with the existing AM and PM travel times for single-occupant vehicle (SOV), HOV, and transit modes on these paths.

During the AM peak period, the travel time for SOVs traveling westbound on I-90 to Seattle from I-405 is approximately 12 minutes. In the eastbound direction, the travel time for SOVs traveling between Seattle and I-405 is approximately 14 minutes. The PM peak-period travel time for SOVs traveling westbound to Seattle from I-405 is about 19 minutes. The travel time for SOVs traveling eastbound from Seattle to I-405 is 17 minutes.

3.5.2.3 Level of Service

The existing LOS on I-90 varies throughout the study area. There is substantial congestion where vehicles travel at stop-and-go conditions (LOS F), and vehicle queues are observed throughout most of the peak periods, especially in the PM peak period. The congestion maps in Exhibit 3-12 illustrate the I-90 mainline LOS.

These congestion maps indicate vehicle speeds over time (vertical axis) and distance (horizontal axis). The time indicated on these maps is a 2.5-hour duration in both the AM (6:30 to 9 a.m.) and PM (3:30 to 6 p.m.) peak periods.

TABLE 3-18
I-90 Existing Travel Times by Mode

Travel Time Path Endpoints		Travel Time (minutes)					
		AM Peak Period			PM Peak Period		
Beginning Point	**Ending Point**	**SOV**	**HOV**	**Transit[a]**	**SOV**	**HOV**	**Transit[a]**
Westbound Outer Roadway							
Mercer Island (Island Crest Way)	I-5 to Downtown Seattle	7	7	-/-	9	9	11/8
Bellevue Way	I-5 to Downtown Seattle	10	10	-/-	17	17	19/-
I-405	I-5 to Downtown Seattle	12	12	-/-	19	18	21/18
Reversible Center Roadway[b]							
Mercer Island (77th Avenue SE)	I-5 to Downtown Seattle[c]	7	N/A	-/-	8	N/A	-/-
Mercer Island (77th Avenue SE)	Seattle (5th Avenue South)[d]	N/A	5	6/6	N/A	5	6/6
Bellevue Way	Seattle (5th Avenue South)[d]	N/A	7	11/-	N/A	8	11/-
I-405	Seattle (5th Avenue South)[d]	N/A	10	13/11	N/A	10	13/11
Eastbound Outer Roadway							
I-5 from Downtown Seattle	Mercer Island (Island Crest Way)	8	8	10/9	12	12	-/-
I-5 from Downtown Seattle	Bellevue Way	12	12	20/-	15	15	-/-
I-5 from Downtown Seattle	I-405	14	14	25/17	17	17	-/-

[a] Numbers are for bus routes with stops on Mercer Island /bus routes with no stops on Mercer Island.
[b] Reversible center roadway operates westbound in the AM peak and eastbound in the PM peak.
[c] SOVs are required to exit/enter the reversible center roadway near Rainier Avenue South.
[d] Travel time is to/from 5th Avenue South via the D2 Roadway.
Note: Travel times are rounded to the nearest minute.
N/A = not applicable because the mode is not eligible to travel this path or the path is not prohibited.
- = Buses do not travel on this roadway during this period and/or do not travel between these points.

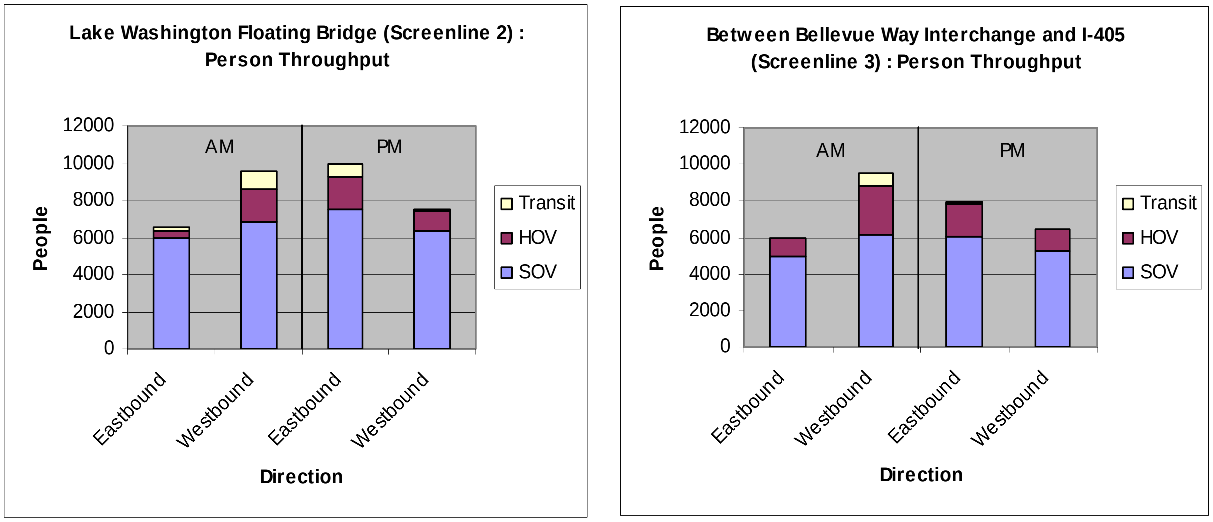

EXHIBIT 3-11
I-90 Existing AM and PM Peak-Hour Person Throughput by Mode at Screenlines 2 and 3

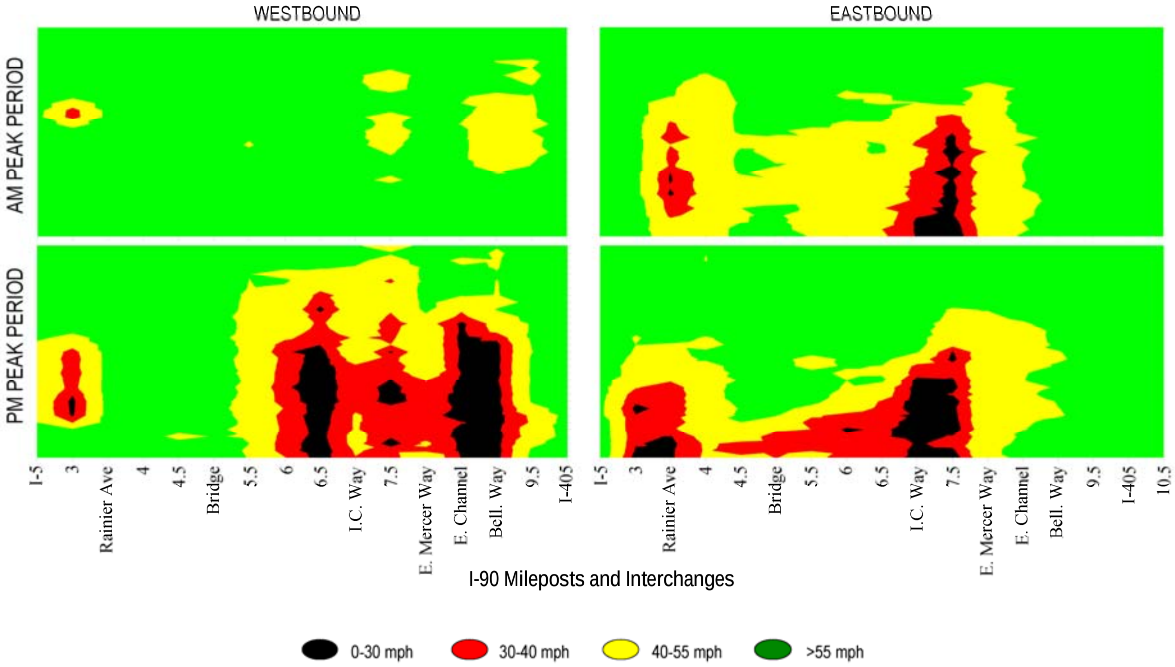

EXHIBIT 3-12
I-90 Existing Year AM and PM Peak-Period Vehicle Speeds in General-Purpose Lanes

The distance covers I-90 from the western terminus at SR 519 to east of the I-405 interchange. Although LOS is based on vehicle density and the congestion maps are based on speed, the two measurements are generally related to one another. On the congestion maps, LOS E and F conditions (speeds at or below 55 mph) are indicated where areas of yellow, red, or black occur. LOS D or better conditions are portrayed by areas of green (vehicle speeds over 55 mph) occur.

During the AM peak period in the westbound direction, I-90 starting east of I-405 operates at LOS E or better until the area between the Rainier Avenue South interchange and the I-5 interchange, which operates at LOS F. Traveling in the eastbound direction, I-90 operates at LOS E or worse from the Rainier Avenue South interchange to the East Mercer Way interchange. East of the East Mercer interchange, I-90 operates at LOS D or better. The reversible center roadway operates at LOS B or better. The greatest congestion is at the western terminus of the reversible center roadway where center roadway vehicles merge back onto the I-90 mainline.

During the PM peak period, westbound I-90 operates at LOS E or worse between Bellevue Way and the First Hill Tunnel in Mercer Island. West of Mercer Island, I-90 then operates at LOS D or better, with the exception of the area just east of I-5, which operates at LOS F due to vehicles merging with I-5 traffic. I-90 in the eastbound direction operates at LOS F between I-5 and the East Mercer Way interchange. Across the East Channel Bridge, I-90 operates at LOS E until the Bellevue Way interchange. East of Bellevue Way, I-90 operates at LOS D or better. The reversible center roadway operates at LOS B or better. The highest congestion is at the western origin of the reversible center roadway where automobiles coming from the D2 Roadway and the I-90 mainline access the reversible center roadway.

3.5.2.4 Freeway Safety

WSDOT's existing I-90 accident data were collected for the 5-year period (2004 to 2008). The accident analysis included the westbound, eastbound, and reversible center roadways. The extent of the analysis was from the I-90 western terminus to just east of I-405, which is slightly more than 8 miles. The corridor-length accident rates for the eastbound, westbound, and center roadways are well below the average accident rate for urban interstate facilities in WSDOT's Northwest Region.

The accident analysis also identified collision analysis locations (CALs) and collision analysis corridors (CACs), as defined by WSDOT. A CAL is a spot location determined to have a clustering rate of severe accidents during the previous 5 years. A CAC is defined as a 5-mile corridor with a 5-year history of at least 11 fatal or serious collisions. No CACs were identified in the study area, and the only CAL was essentially I-90 between the Bellevue Way and I-405 ramps near the eastern edge of the East Link Project study area.

3.5.3 Environmental Impacts

This section describes the physical and operational changes on I-90 resulting from the No Build Alternative and from implementation of light rail for the years 2020 and 2030. Consistent with the *SR 520, I-5 to Medina: Bridge Replacement and HOV Project Supplemental Draft EIS* (WDSOT, January 2010), SR 520 improvements and tolling strategies are assumed to be in place by year 2020; therefore, the East Link Project assumed these improvements in both future year conditions.

Although the entire I-90 Two-Way Transit and HOV Operations Project is expected to be completed before beginning construction of the East Link Project, the East Link Project was compared to two different No Build Alternatives along I-90. HOV traffic would be moved from the center roadway to the outer roadways when construction of the East Link Project begins. Stage 1 of the I-90 Two-Way Transit and HOV Operations Project was recently completed and Stage 2 is being constructed, but Stage 3 might not be completed until just before East Link construction on I-90 begins. If the entire I-90 Two-Way Transit and HOV Operations Project is completed well before East Link construction begins, then the reversible center roadway would be available for vehicle use as well as the new HOV outer roadway lanes. Because the HOV lanes in the outer roadway might not be completed until just before construction of East Link, the following two No Build Alternatives were analyzed:

1. One with the Stage 3 HOV lanes completed immediately before East Link construction on I-90, so HOVs and transit can shift from the center roadway to the outer roadway HOV lanes. In this scenario, the new HOV lanes in the outer roadway would never operate in conjunction with the center roadway. This is referred as the No Build Alternative with Stages 1 and 2 only.
2. One with the Stage 3 HOV lanes completed and the center roadway available for transit, HOV, and Mercer Island drivers. In this No Build Alternative, both the center roadway and outer HOV lanes are open the entire distance between Seattle and Bellevue. This is referred to as the No Build Alternative with Stages 1 through 3.

Exhibit 3-13 is a schematic of the three stages of the I-90 Two-Way Transit and HOV Operations Project, and Exhibit 3-14 provides the I-90 configurations between Seattle and Mercer Island with and without East Link. The following subsection describes the proposed future access and circulation modifications to I-90. These changes were incorporated into the 2020 and 2030 No Build Alternative and East Link travel forecasts (Section 3.5.3.2) and in the operational and safety analysis (Section 3.5.3.3). The *Transportation Technical Report* further describes these future access and circulation modifications.

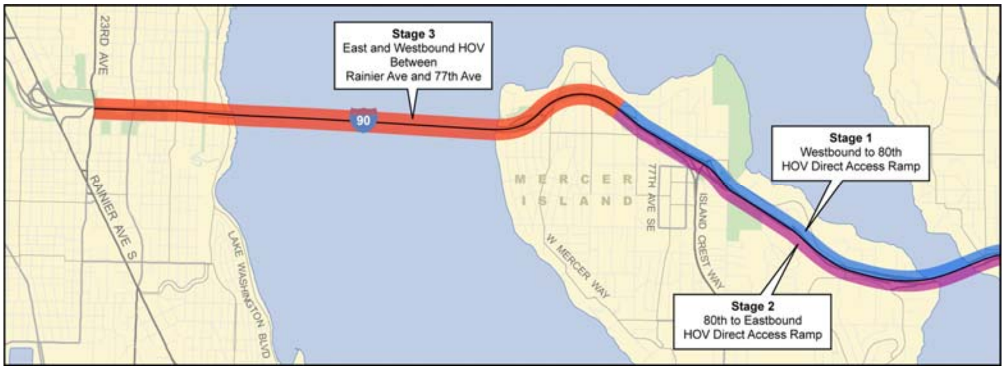

EXHIBIT 3-13
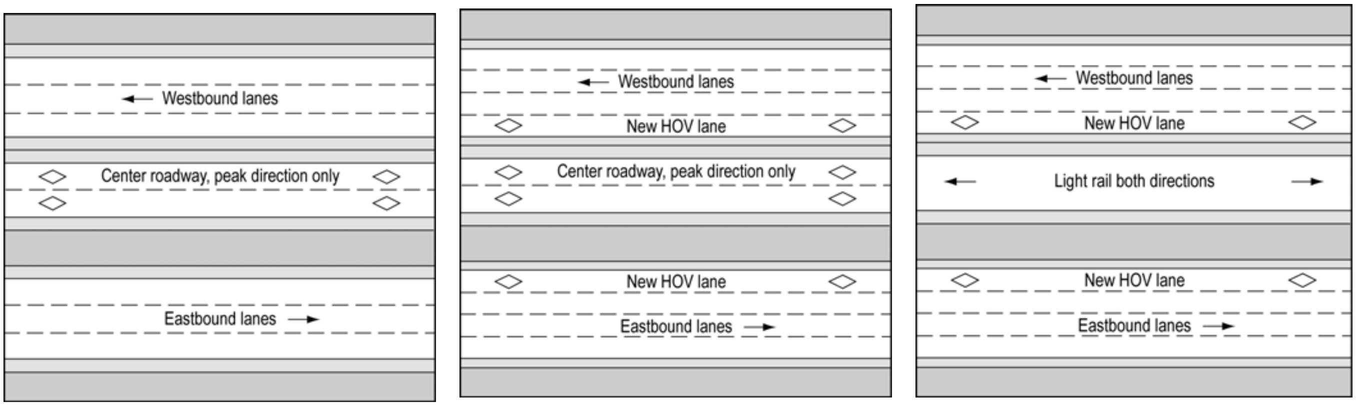
I-90 Two-Way Transit and HOV Project Stages

3.5.3.1 Access and Circulation Modifications

Preferred Interstate 90 Alternative (A1)

Access and circulation along the I-90 corridor will be modified in the No Build Alternative by the I-90 Two-Way Transit and HOV Operations Project. With the East Link Project, access and circulation modifications would affect the D2 Roadway, access to the reversible center roadway, eastbound HOV access near Mercer Island, and potentially the HOV ramps connecting to Bellevue Way SE.

With the East Link Project, the *Preferred Alternative* includes joint operations of buses and light rail for the D2 Roadway that connects the south area of Downtown Seattle with the I-90 center roadway. A operational option is also evaluated that includes rail-only operations on the D2 Roadway. HOVs would not be allowed to use this roadway in either condition with the East Link Project. For the operational option that has exclusive light rail in the D2 Roadway, buses would be rerouted to other roadways to access I-90 from the south area of Downtown Seattle (such as 4th Avenue South via SR 519).



I-90 Existing Conditions

I-90 Two-Way Transit and HOV Project

I-90 with Preferred Alternative A1

EXHIBIT 3-14
I-90 Configuration Before and After East Link

During East Link construction and operations, access to and from the I-90 reversible center roadway would be removed as well as its ramps connecting to Mercer Island (77th Avenue SE and Island Crest Way). With the access modifications from the I-90 Two-Way Transit and HOV Operations Project and the changes in access with light rail construction, the traffic analysis assumed Mercer Island SOVs would be able to use the HOV lanes in both directions of I-90 between Seattle and Island Crest Way to demonstrate that it does not affect the results of the East Link analysis and represents a worst case condition. This assumption does not represent approval of SOVs using the outer roadway HOV lanes or the eastbound left-side off-ramp to Island Crest Way. Any changes to the HOV lane eligibility such as tolling or managed lanes or Mercer Island SOV use would be addressed in a future analysis, approval, and agreement.

As part of the *Preferred Alternative A1*, an eastbound HOV off-ramp to would be constructed at Island Crest Way. In lieu of providing this HOV off-ramp at Island Crest Way, a design option to construct the eastbound HOV off-ramp at 77th Avenue SE was considered. A second design option that would construct neither of these eastbound HOV off-ramp options was also evaluated. With this design option, all HOV and bus traffic would utilize the eastbound general-purpose ramps at 77th Street and Island Crest Way to access Mercer Island. With either the *Preferred Alternative* or the design options, the existing eastbound general-purpose off-ramps at Island Crest Way and 77th Avenue SE would remain.

Preferred 112th SE Modified Alternative (B2M) and other Segment B Alternatives

In Segment B, *Preferred Alternative B2M* would preserve both the westbound HOV on-ramp and eastbound HOV off-ramps at the I-90 and Bellevue Way SE interchange by exiting the center roadway on a new elevated structure over the westbound mainline. With *Preferred Alternative B2M* and Alternatives B2A, B2E, B3, B3 – 114th Extension Design Option, and B7, a design option is considered that would preserve only the westbound HOV on-ramp. Specific to Alternative B1, another design option is considered that would close both westbound general-purpose and westbound HOV ramps as the light rail track would use the space currently used by both ramps beneath the westbound mainline roadway. However, WSDOT's preference is to maintain both the westbound HOV on-ramp and the eastbound HOV off-ramp at this interchange. This would require modifying the design for all nonpreferred alternatives that use Bellevue Way SE. The analysis of these access modifications is discussed in Section 3.5.3.3, Highway Operational and Safety Impacts.

3.5.3.2 Traffic Forecasts

Vehicle traffic and transit ridership forecasts for I-90 were prepared using the PSRC and Sound Transit travel demand models, as discussed in Section 3.3.3. The overall AM and PM peak-period growth rates to the year 2030 are estimated to be between 1 and 2 percent with the higher growth forecasted in the non-peak direction (eastbound in the morning and westbound in the afternoon). By year 2030, the peak-period demand in each direction would become more balanced than today as the population and employment density on the Eastside increases. With the project, slightly less vehicle traffic growth was predicted compared to the no-build condition, as the model predicts people would shift from driving to riding light rail. This is because East Link would provide a more reliable mode of travel with substantial travel-time savings compared to a vehicle travelling in a congested regional roadway network, especially between the urban centers of Seattle and Bellevue.

As part of the forecasting, the SOV, HOV, and transit mode shares were calculated both with and without East Link. As expected with more congestion, the forecasts for the future No Build Alternative suggest that people would slightly shift toward HOV and bus usage. With the East Link Project, the forecasts suggest a substantial shift to transit across Lake Washington (Screenline 2), compared to the No Build Alternative, because light rail would provide shorter travel times than other transportation choices.

By 2030, the transit mode share percentage across Lake Washington (SR 520 and I-90) would increase by up to 33 percent from the No Build Alternative (Table 3-19). People would readjust their mode choices and choose to ride light rail because of faster travel times when compared to bus or auto modes. The overall transit mode share (combined eastbound and westbound) on I-90 alone would more than double from about a 10 and 7 percent share (AM and PM conditions) without the project to slightly over a 20 percent share with the project in both AM and PM conditions. The pie charts in Exhibit 3-15 compare mode share between the No Build Alternative and East Link on I-90 in the year 2030 at Screenline 2. In conjunction with the increased transit mode share increase, the SOV and HOV mode share would decrease as people choose to ride light rail.

At Screenline 3, the transit mode share shifts would be less pronounced with the project because light rail would not cross the screenline. Slight changes in mode share are forecast at Screenline 3 in 2020 and 2030 with East Link.

3.5.3.3 Highway Operational and Safety Impacts

Based on the traffic forecasts discussed in Section 3.5.3.2, freeway operations during the AM and PM peak periods were analyzed for years 2020 and 2030. The following measures were used to assess potential project impacts on I-90:

- Vehicle and person throughput and capacity
- Vehicle and person demand served
- Travel time
- Congestion and LOS
- Safety

Person and Vehicle Throughput and Capacity

Vehicle and person throughput on I-90 was tabulated at Lake Washington (Screenline 2) and Mercer Slough (Screenline 3) in the SOV, HOV, and transit modes. Transit includes both bus and light rail passengers for the project alternatives.

With East Link, the overall person throughput across Lake Washington (Screenline 2) in the AM and PM peak hours in 2030 would increase by about 5,300 people (about 30 percent) compared to the No Build Alternative with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed. Throughput would increase by about 2,600 people (about 15 percent) compared to the No Build Alternative with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project completed (Exhibit 3-16).

One of the key reasons the East Link Project would transport more people across I-90 is because bidirectional light rail would be a more efficient use of the center roadway space than the current reversible one-directional vehicle operations. The roadway's restricted access and egress also limit vehicle capacity and throughput.

TABLE 3-19
Screenline 2 Existing, 2020, and 2030 Mode Share for I-90 and SR 520

Direction	Existing	2020 SOV/HOV/Transit Mode Share (Percent)			2030 SOV/HOV/Transit Mode Share (Percent)

EXHIBIT 3-16
I-90 2030 AM and PM Peak-Hour Person Throughput across Lake Washington

Compared with the No Build Alternative, the East Link project would also increase the I-90 person capacity across Lake Washington as light rail in the center roadway would serve both directions of travel at all times and would provide a substantial capacity increase over the existing reversible center roadway. Along I-90, the project would use dedicated right-of-way, allowing East Link to operate reliably, independent of congested roadway conditions. The project is planned to operate during the peak periods with a train-arrival frequency (i.e., headway) of every 7 minutes by 2030. The project could carry 600 persons per four-car train comfortably and 800 persons during crowded conditions, operated with 4-minute headways; this would more than double the person-carrying capacity of I-90, as East Link could carry a total of 18,000 to 24,000 people (9,000 to 12,000 per direction) during the peak period. This is the equivalent of about seven to ten freeway lanes of traffic (assuming that automobiles in the Puget Sound region average 1.17 persons per vehicle during commute hours, or about 2,300 persons per hour per freeway lane). The following subsections present the vehicle and person throughput results at Screenlines 2 and 3.

Screenline 2 (I-90 across Lake Washington)

At Screenline 2, compared to both No Build Alternatives, person throughput would be substantially higher with the project for both AM and PM peak hours in 2020, as indicated in Table 3-20 and Exhibit 3-17. The greatest increase in person throughput is expected in the reverse-peak direction on I-90 (reverse peak is defined as eastbound in the AM peak period and westbound in the PM peak period) because light rail would provide a more reliable transportation option and would provide capacity in the direction opposite of vehicle travel in the reversible center roadway (no-build conditions only). In the reverse-peak directions, there would be no modification to the I-90 roadway (vehicular) capacity across Lake Washington.

Overall, the East Link Project would increase total person throughput by 14 to 25 percent compared to the no-build condition (with Stages 1 through 3 or Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project, respectively) in the 2020 AM peak hour, and a 5 to 21 percent increase in the PM peak hour, respectively.

In 2030, the East Link Project would increase total person throughput by 18 to 29 percent in the AM peak hour and 9 to 31 percent in the PM peak hour compared to the two no-build conditions. In every comparison with the No Build Alternative, the person throughput with East Link is higher in the westbound direction in year 2020 and 2030, higher in the eastbound direction in the AM peak hour (reverse-peak direction), and slightly lower (less than 4 percent in 2030) for the eastbound direction in the PM peak hour.

The lower eastbound PM person throughput is because of a relatively low throughput in the eastbound HOV lane that crosses the screenline. Lane changing associated with the transition of the general-purpose lane to an HOV lane near the Rainier Avenue South interchange and the additional vehicles involved in the lane changing due to the center roadway closure result in reduced throughput in the HOV lane. If the lane were managed to accommodate more people, the throughput should be comparable for the no-build and build conditions.

In terms of vehicle throughput, the project would have a similar to higher vehicle throughput compared to either of the two no-build conditions in the reverse-peak directions because roadway capacity would be unaffected in combination with people riding light rail. People riding light rail would slightly reduce congestion and, therefore, increase vehicle throughput.

[b] With Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.
[c] Numbers indicate percent change between No Build Alternative (Stages 1 and 2) and East Link/ percent change between No Build Alternative (Stages 1 through 3) and East Link.
Note: Due to rounding, values may not sum correctly.

Although in most cases the East Link Project would increase the person throughput in the peak direction (the peak direction is westbound in the AM peak period and eastbound in the PM peak period), the vehicle throughput in the peak direction would be similar to improved compared to the No Build Alternative (with Stages 1 and 2 of I-90 Two-Way Transit and HOV Operations Project) or slightly reduced compared to the No Build Alternative (with Stages 1 through 3 of I-90 Two-Way Transit and HOV Operations Project). This decrease is due to a relatively low throughput in the eastbound HOV lane that crosses the screenline, as previously discussed. Table 3-20 provide Screenline 2 vehicle throughput for years 2020 and 2030.

Person and vehicle throughput at Screenline 2 for both the 77th Avenue SE eastbound HOV off-ramp design option and the design option without an HOV eastbound off-ramp to Mercer Island are expected to be similar (within 3 percent) to *Preferred Alternative A1* with the eastbound HOV off-ramp at Island Crest Way. These access modifications are not expected to substantially affect I-90 mainline operations because connections to Mercer Island residents to the south currently exist.

The operational option at the D2 Roadway and design option at the I-90 at Bellevue Way interchange would have person and vehicle throughput across Screenline 2 similar to the *Preferred Alternative A1*.

Screenline 3 (Mercer Slough)

Compared to Screenline 2, changes in throughput at Screenline 3 would be fewer between the no-build and build conditions because light rail would not cross this screenline and HOV lanes are already provided in this area. For the 2020 and 2030 total person throughput at Screenline 3, the East Link Project would increase total person throughput in both of the AM and PM peak hours when compared to the No Build Alternative with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project completed. Total person throughput would remain similar if Stage 3 of the I-90 Two-Way

Transit and HOV Project is completed as indicated in Table 3-21 and Exhibit 3-18.

The build condition would accommodate a higher person throughput than either of the two no-build conditions in the reverse-peak direction (eastbound in the AM and westbound in the PM). This is because the vehicle capacity would not change in this direction and people would choose to ride light rail. As people shift to ride light rail, vehicle congestion would decrease slightly and, therefore, vehicle throughput would increase.

In the peak directions (westbound in the AM and eastbound in the PM), the build condition would generally increase person throughput compared to the no-build condition with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed, but would be similar or slightly decrease when compared to the no-build condition that includes Stage 3. This decrease in person throughput is most noticeable in the eastbound direction during the PM peak hour. As noted in the Screenline 2 (Lake Washington) discussion, the reduced eastbound (PM peak) HOV throughput would reduce the HOV throughput at Screenline 3.

In the 2020 and 2030 reverse-peak directions (eastbound in the AM and westbound in the PM), the vehicle throughput in the build condition would increase compared to either of the two no-build conditions, and would be similar or decrease in the peak directions; reasons for these changes are discussed earlier in this section. Overall, total vehicle throughput across Screenline 3 would increase compared to the no-build condition with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed, and would be similar compared to the no-build condition that includes Stage 3. Table 3-21 provide Screenline 3 vehicle throughput for years 2020 and 2030.

EXHIBIT 3-18
2020 and 2030 I-90 Peak-Hour Person Throughput by Mode at Mercer Slough (Screenline 3)

Vehicle and Person Demand Served

In conjunction with person and vehicle throughput, the percentage of the forecasted travel demand that can be accommodated was evaluated. This measure compares the person and vehicle throughput with the expected demand across each screenline. A percent served value less than 100 indicates congested conditions that limit the number of vehicles (or people) crossing the screenline. The ability to serve more of the demand indicates that congestion patterns might not be as significant and that congestion might not occur for as long a period. Table 3-22 provides the vehicle and person demand served across Screenlines 2 and 3 for year 2030 conditions.

At Screenline 2, the AM and PM peak-hour total (combined eastbound and westbound directions) vehicle- and person-demand served percentage would increase in the build condition compared to both no-build conditions. Total vehicle percent demand served would increase between 14 and 22 percent in the build condition compared to the no-build condition with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed; the increase would be between 2 and 4 percent with Stage 3 completed. Total person percent demand served would increase between 19 and 24 percent in the build condition compared to the no-build conditions with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed; the increase would be between 6 and 9 percent with Stage 3 completed. At Screenline 3, the build condition total (eastbound and westbound directions) vehicle and person demand served would increase between 9 and 17 percent compared to the no-build condition with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project completed. Compared to the no-build condition when Stage 3 is completed, the vehicle and person demand served would increase up to 4 percent.

Travel Time

In the 2020 and 2030 no-build conditions, travel times would continue to become longer as congestion would increase in the future. Table 3-23 lists 2020 and 2030 AM and PM peak-period travel times for SOVs, HOVs, and transit between Seattle and I-405, and the *Transportation Technical Report* (Appendix H1) further describes and compares the travel times. It is expected

[a] With Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project.
[b] With Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.

that by 2030 in the no-build condition, SOV travel time from I-405 to Seattle in the AM peak period could more than double and take up to 27 minutes. In the eastbound direction, SOV travel time could increase by approximately 50 percent and would be close to 21 minutes. In the PM peak period, a similar increase in travel time is expected. In the westbound direction, to go from I-405 to Seattle, the trip would take close to 30 minutes—an increase of about 60 percent from existing conditions. In the eastbound direction, an SOV going from Seattle to I-405 could take close to 19 minutes. The following subsections provide travel time comparisons for each of the three modes (SOV, HOV, and transit) between the no-build conditions and conditions with the East Link Project.

SOV

With light rail in 2020 and 2030, SOV travel times in the AM peak period are expected to decrease by approximately 5 minutes in the westbound direction and increase by up to 4 minutes in the eastbound direction when compared to the No Build Alternative (with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project) in the AM peak period. In the 2020 PM peak period, SOV travel times are expected to be similar (eastbound direction) or improve by up to 8 minutes (westbound direction) when compared to the No Build Alternative with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project. By 2030, smaller travel time improvements in the PM peak period are expected as congestion would increase in the build condition. In the 2030 PM peak period, SOV travel times with East Link would improve by 6 minutes in the westbound direction and travel times would be similar in the eastbound direction compared to the No Build Alternative with the I-90 Two-Way Transit and HOV Project Stages 1 and 2. Westbound travel time improvements would be attributed to a shift from people driving their automobiles to riding light rail and the additional capacity provided with the outer roadway HOV lanes.

In year 2020, SOV travel times with East Link compared to the No Build Alternative that assumes the I-90 Two-Way Transit and HOV Project Stages 1 through 3 are completed would be similar (eastbound direction) or improve by up to 3 minutes (westbound direction) in the AM peak period. Travel time comparisons in the PM peak period would be similar to. In year 2030, SOV travel time comparisons between these two conditions in the AM peak period would be similar to those in 2020. In the PM peak period, westbound travel times with light rail are expected to improve by approximately 6 minutes and improve by about 2 minutes in the eastbound direction compared to the No Build Alternative, assuming that I- 90 Two-Way Transit and HOV Operations Project Stages 1 through 3 are completed.

SOV travel times between Seattle and Mercer Island would remain similar or improve by as much as 2 minutes with East Link compared to the No Build Alternative, except in the PM eastbound direction. In this direction, travel times from Seattle to Mercer Island would take between 6 (using the reversible roadway) and 12 (using the eastbound mainline roadway) minutes with the No Build Alternative, but would take about 11 minutes with East Link. For trucks, a similar travel time comparison between the no-build conditions and the East Link Project would be expected because they also travel in the general-purpose lanes.

HOV and Bus Transit

HOV and bus travel times on I-90 in years 2020 and 2030 under the No Build Alternative (with only the I-90 Two-Way Transit and HOV Operations Project Stages 1 and 2) would stay similar or get longer than existing conditions as congestion would increase in the future. HOV and bus travel times would be similar in the peak direction and improve in the reverse-peak direction for East Link and the No Build Alternative that assumes the I-90 Two-Way Transit and HOV Project is completed (Stages 1 through 3) compared to existing conditions. In the AM and PM peak periods, it could take between 10 and 15 minutes for an HOV to travel between Seattle and I-405 for the No Build Alternative (with only Stages 1 and 2).

For the No Build Alternative (Stages 1 through 3), HOV travel between Seattle and I-405 could take between 10 and 17 minutes. With East Link, it would take between 11 and 15 minutes. Buses traveling along I-90 in the reverse-peak direction would be expected to have similar or improved travel times because the outer HOV lane would provide buses with a faster lane than the general-purpose lanes they would be required to use when the reversible center roadway would be operating in the opposite direction. In the peak directions, buses travelling between Seattle and I-405 would have up to 3 minutes longer travel time with the East Link Project than in either of the no-build conditions.

Light rail travel between Seattle and Mercer Island and between Seattle and Bellevue Way would take 8 and 12 minutes, respectively; this would be a substantial improvement compared to an SOV trip, which could take up to 15 minutes between Seattle and Mercer Island and up to 24 minutes between Seattle and Bellevue Way in the No Build Alternative.

[a] The No Build Alternative with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project.

[b] The No Build Alternative with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.

[c] "Bld" represents the East Link Project 's *Preferred Alternative A1* (joint bus/light rail operations in the D2 Roadway, an eastbound HOV direct-access off-ramp at Island Crest Way, and both eastbound and westbound HOV direct-access ramps preserved at Bellevue Way).

[d] Numbers are for transit routes with stops on Mercer Island /transit routes with no stops on Mercer Island.

[e] Reversible center roadway operates westbound in the AM peak and eastbound in the PM peak for the No Build Alternative; it would be used by light rail with the project.

[f] Travel time is to/from 5th Avenue South via the I-90 D2 Roadway.

[g] Light rail travel time between International District/Chinatown Station and South Bellevue Station.

Note: Travel times are rounded to the nearest minute.

N/A = not applicable because the mode is not eligible to travel this path or the path is not prohibited.

NB = No Build Alternative

- = Buses do not travel on this roadway during this period and/or do not travel between these points.

The *Preferred Alternative A1* assumes joint use of the D2 Roadway. For the operational option that has exclusive light rail use in the D2 Roadway, buses would be rerouted to other roadways to access I-90 from South Seattle (such as 4th Avenue South), and the bus travel time would increase. With the *Preferred Alternative A1*, buses would experience up to a 2-minute savings inbound in the AM peak period to Downtown Seattle and experience up to a 6-minute savings outbound in the PM peak period from Downtown Seattle on I-90 compared to the operational option in which buses are not eligible to use the D2 Roadway. Some of this savings would be reduced when buses travel along 5th Avenue South to and from D2 Roadway. It would take up to 2 additional minutes of time to travel along 5th Avenue South compared to 4th Avenue South. Additionally, depending on the joint-use operating policy of the D2 Roadway, up to 3 additional minutes of average delay, in either direction, could be incurred by buses while waiting for clearance to enter the D2 Roadway. However, during evening events at the stadiums, bus routes along 4th Avenue South would incur additional travel time due to increased congestion along this street.

For the design option with an HOV off-ramp to 77th Avenue SE, HOV and bus travel times are expected to be approximately 1 to 2 minutes faster in both the AM and the PM peak hours when compared to the Island Crest Way off-ramp in the *Preferred Alternative A1*. Compared to the *Preferred Alternative A1*, HOV and bus travel times are similar in both AM and PM peak hours for the design option that does not include an eastbound HOV off-ramp and uses the 77th Avenue SE general purpose ramp only.

The preferred alternative preserves both the eastbound and westbound HOV ramps from I-90 to Bellevue Way SE as preferred by WSDOT. For the design option at I-90 and Bellevue Way interchange that would close the eastbound HOV off-ramp to Bellevue Way, HOVs using this ramp would reroute to use the general-purpose Bellevue Way off-ramp. Closing the eastbound HOV ramp would have a negligible effect on travel time for HOVs, as minimal congestion is expected between Mercer Island and the Bellevue Way interchange. This is a result of the I-90 Two-Way Transit and HOV Operations Project improvements, which include an auxiliary lane between East Mercer Way and I-405 ramps.

For Alternative B1, which closes the westbound direct-access HOV on-ramp from Bellevue Way, HOVs traveling between Bellevue and Seattle would use the general-purpose Bellevue Way on-ramp and weave across the general-purpose lanes to enter the HOV lane. This maneuver would increase the westbound HOV travel time from Bellevue Way to Seattle by approximately 8 to 12 minutes, depending on the peak period.

With any operational option at the D2 Roadway or design option at the eastbound Mercer Island HOV off-ramp or HOV ramps at the Bellevue Way interchange, the travel times for the other vehicles (SOV and trucks) on I-90 would not be expected to change from the travel times already described.

Congestion and Level of Service

Congestion on I-90 is expected to be worse in the future, as indicated by longer travel times described in the previous section. Therefore, the LOS on I-90 would continue to degrade and generally operate at LOS E or F conditions throughout the peak periods with the No Build Alternative. Without light rail, increased congestion on I-90 is expected to occur for longer distances and longer periods each day. More congestion and longer travel times would make travel more difficult between Seattle and Bellevue, two of the key employment and population centers of Puget Sound. Congestion and resulting vehicle hours of travel would be expected to extend for longer periods, exceeding 3 hours for each peak period. Without light rail's ability to move more people, an imbalance in vehicle capacity with the reversible center roadway across I-90 would impede efficient and reliable transit service to the growing residential and commercial areas on the Eastside.

The congestion maps in Exhibit 3-19 indicate vehicle speeds over time (vertical axis) and distance (horizontal axis) for the year 2030. The time indicated on these maps is for a 2.5-hour duration in both the AM (6:30 to 9 a.m.) and PM (3:30 to 6 p.m.) peak periods. The distance covers I-90 from the western terminus (west of I-5) to east of the I-405 interchange. On the map, areas with yellow, red, and black are generally considered LOS E or F conditions with vehicle speeds typically at or below 55 mph. Green areas generally indicate LOS D or better conditions with vehicle speeds over 55 mph. This section focuses on year 2030 conditions, as the comparison between no-build and build conditions in year 2020 is similar to year 2030.

In the AM peak period, congestion in the westbound direction would slightly improve under the No Build Alternative if the I-90 HOV lanes are completed by the I-90 Two-Way Transit and HOV Operations Project (Stages 1 through 3). With the East Link Project, congestion in the westbound direction would have traits similar to those of the No Build Alternative with the I-90 Two-Way Transit and HOV Project Stages 1 and 3, although less congestion would occur across the I-90 bridge. In the eastbound direction with East Link operating, there would be less AM peak congestion between the I-5 and Mount Baker Tunnel area as people shift modes and ride light rail.

In the PM peak period, the freeway LOS would generally operate at LOS E or F conditions throughout the peak period. The center roadway would continue to be underutilized because access is constrained by congested roadways and traffic signals. These constraints reduce the ability to move high volumes of people to and from key urban centers across the lake. With the project, congestion in the westbound direction would be substantially reduced compared to either of the two no-build conditions; as a result of people riding light rail in the corridor. In the eastbound direction, congestion would be heavier in the Rainier Avenue South interchange and Mount Baker Tunnel area because the reversible center roadway would be closed, but there would be less congestion east of this area, near Mercer Island, because slightly less vehicle throughput could occur at the Rainier Avenue South/Mount Baker Tunnel area.

With the operational option to have exclusive light rail in the D2 Roadway, there would be no change in the eastbound or westbound congestion on I-90 in the AM or PM peak period compared to the *Preferred Alternative A1*. AM and PM peak period congestion on I-90 would also be comparable between the *Preferred Alternative A1* and either of the eastbound Mercer Island HOV off-ramp design options. If either of the Bellevue Way HOV direct-access ramps (westbound on-ramp and eastbound off-ramp) were closed, the impact on I-90 congestion would be nearly negligible. Minor variations would occur, but they would not be noticeable enough to affect overall congestion.

In addition to the general I-90 operating conditions, the performance of the HOV lanes was evaluated to identify where they would fail to meet WSDOT’s HOV Speed and Reliability Standard of vehicles travelling at least 45 mph during the peak commuting hour 90 percent of the time. It was assumed in the traffic analysis that, in no-build conditions, Mercer Island SOVs would not be allowed in the outer roadway HOV lanes but would have access to the center roadway. However, in the build condition, all vehicles traveling to and from Mercer Island were assumed for the traffic analysis to be able to use the outer roadway HOV lanes. This assumption does not represent approval of SOVs using the outer roadway HOV lanes. Any changes to the HOV lane eligibility such as tolling or managed lanes or Mercer Island SOV use would be addressed in a future analysis, approval, and agreement.

During the AM peak period in the 2030 no-build condition, the westbound HOV lane would not meet WSDOT’s HOV Speed and Reliability Standard near Rainier Avenue South, as the lane transitions from an HOV lane to a general-purpose lane and vehicles begin to slow due to the congestion in the general-purpose lanes. In the 2030 *Preferred Alternative* condition, the westbound HOV lane would meet WSDOT’s HOV Speed and Reliability Standard at all locations in the westbound direction.

In the eastbound direction, the HOV lane in both the 2030 no-build and *Preferred Alternative* conditions would meet WSDOT’s HOV Speed and Reliability Standard at all locations except Rainier Avenue South interchange, where the general-purpose lane transitions to an HOV lane and vehicles begin to accelerate as they leave the congested general-purpose lanes.

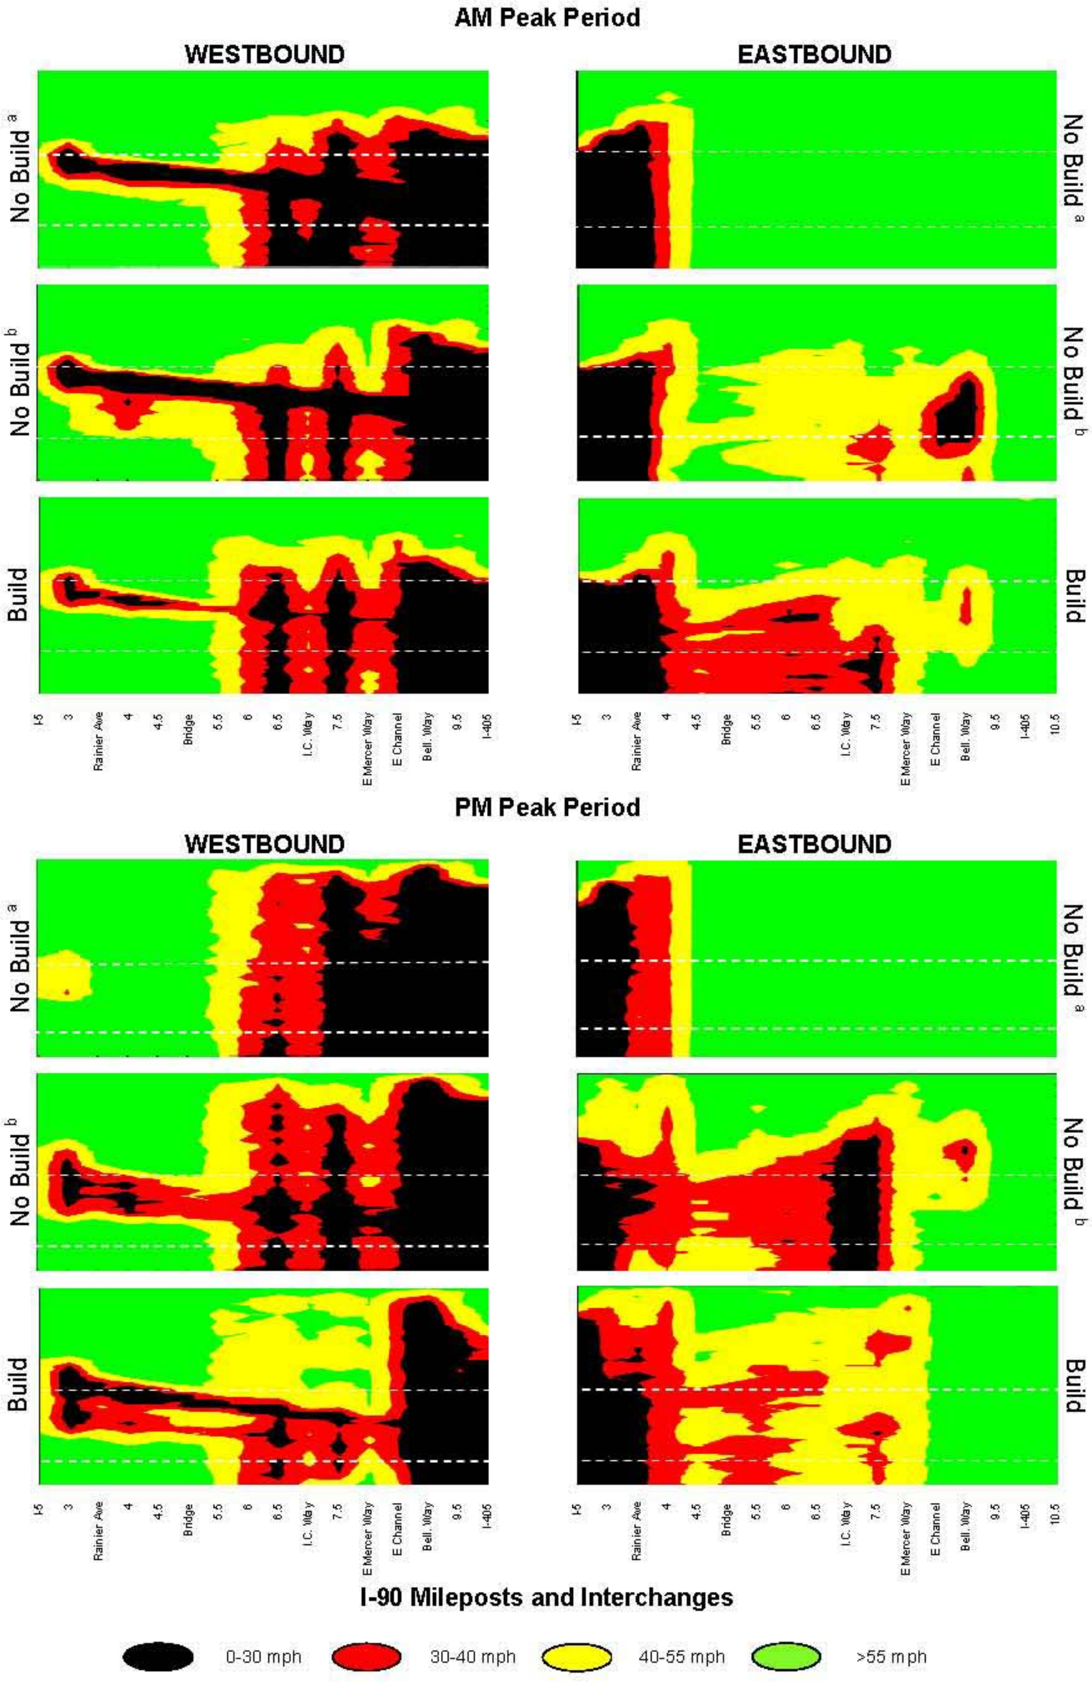
With the project, under the design option where the westbound HOV direct-access on-ramp from Bellevue Way is closed (Alternative B1), HOVs would use the general-purpose on-ramp and weave across the general-purpose lanes to enter the HOV lane. This would likely occur near Island Crest Way and would degrade the HOV lane performance at this location as vehicles travel at slow speeds.

During the PM peak period in the 2030 no-build condition, the westbound HOV lane would have some increased congestion between Island Crest Way and Rainier Avenue South. In the 2030 *Preferred Alternative* condition, the westbound HOV lane would meet WSDOT’s HOV Speed and Reliability Standard in all locations except near Rainier Avenue South, where a small amount of congestion would be expected due to the weaving described in the previous paragraph.

In the 2030 no-build condition, the eastbound HOV lane would meet WSDOT’s HOV Speed and Reliability Standard. In the 2030 *Preferred Alternative* conditions, the eastbound HOV lane would perform similarly to the no-build condition except that it would operate worse at the transition to an HOV lane near Rainier Avenue South due to weaving.

Safety

Implementing the East Link Project would not increase the total number of accidents in the corridor because the number of accidents in the corridor would be similar to no-build conditions. Overall, with more people moving across Lake Washington with East Link and a similar number of accidents, the overall collision rates on I-90 would improve with the project.



[a] The No Build Alternative with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project.

[b] The No Build Alternative with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.

EXHIBIT 3-19
I-90 Year 2030 AM and PM Peak-Period Vehicle Speeds in General-Purpose Lanes

The methodology used to predict future accident frequency for the I-90 roadways is predicated on the basis that accident rates are not uniform throughout the day. As volumes increase and congestion worsens, the accident frequency increases, resulting in higher peak-period accident rates. Based on the I-90 patterns observed, existing accident rates (using 2004 to 2008 accident data) were calculated for four time periods—morning, afternoon, midday, and evening—plus early morning periods. Additionally, a qualitative assessment regarding the proposed access changes with the East Link Project was prepared. Specifically, access modifications that might influence lane changes from a general-purpose on-ramp to the center roadway or outer roadway HOV lane and from the center roadway or outer roadway HOV lane to a general-purpose off-ramp.

It was estimated that, in 2030, East Link would have no impact on the total number of crashes in the I-90 corridor (the westbound outer roadway, eastbound outer roadway, and reversible center roadway combined). East Link would replace the vehicle operations in the reversible center roadway with light rail; as a result, the six to seven annual vehicle accidents predicted in the reversible center roadway would be eliminated. This number is offset by the expected increase in vehicle accidents in the outer mainline roadways as East Link shifts vehicles to the outer eastbound and westbound roadways. When East Link is constructed, the higher VMT in the outer mainline roadway can result in a 1.4 percent increase (a potential for five additional accidents per year) in crashes when compared to the No Build Alternative with the I-90 Two-Way Transit and HOV Project Stages 1 through 3.

Measuring the accident rate in terms of how many people are moved across the lake is another method for assessing safety with the development of the light rail system. Because more people would travel through the corridor with the East Link Project and the expected accident frequency is expected to be similar to the No Build Alternative, the accident frequency on I-90 in terms of moving people would be lower. Overall, the East Link Project would eliminate the potential vehicle conflicts for all modes in the center roadway, improving traveler safety.

Specific to the D2 Roadway operations with light rail, if designated for joint use with buses, there would be about 30 vehicles (including light rail) per hour during the peak periods, or a vehicle about every 2 minutes using this roadway. This number of light rail and bus vehicles would be substantially less than the maximum number of vehicles for safe operations that was determined for Central Link and the bus/light rail joint operations in the Downtown Seattle Transit Tunnel. The findings from the *Central Link Initial Segment Environmental Assessment* (Sound Transit, 2002) established that 60 buses and up to 10 trains per hour would operate jointly. To provide safer vehicle separation and management of bus and light rail vehicle movements on the D2 Roadway, a vehicle identification and signal system would be installed. In addition, bus on-ramps to the D2 Roadway would be equipped with gates to prevent vehicles from entering this roadway. These gates would be raised when buses designated to enter the D2 Roadway are detected.

Qualitative Safety Review of Lane Changes near Interchanges

As mentioned earlier, a qualitative assessment was completed of lane changes from a general-purpose on-ramp to the center roadway or outer roadway HOV lane and from the center roadway or outer roadway HOV lane to a general-purpose off-ramp. This assessment only compared the build condition to the no-build condition with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project completed, as these two conditions include the completed outer roadway HOV lane. Data used in this assessment were based on the 2030 peak-hour throughput presented earlier in this section.

In the no-build condition, the reversible center roadway is open to westbound HOVs and Mercer Island traffic in the AM peak hour and eastbound HOVs and Mercer Island traffic in the PM peak hour; therefore, the East Link Project would result in no physical roadway differences in the off-peak direction, except for eastbound I-90 through downtown Mercer Island where the proposed ramp options result in slight differences during both AM and PM peak periods. Thus, the review of weaving volumes focuses on the following three lane-changing movements:

- **Westbound I-90 from the center roadway or the HOV lane to the ramp to I-5 northbound (AM peak hour) and northbound I-5 to the eastbound I-90 entrance into the center roadway or the HOV lane (PM peak hour):** The number of lane changes to/from I-90 and the northbound I-5 ramps in the peak travel direction for the AM and PM peak hour would likely decrease with the East Link Project due to the closure of the center roadway. This should reduce the potential for related incidents in the build condition compared to the no-build condition with Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project completed.
- **76th Street westbound on-ramp to the HOV lane (AM peak hour):** The 76th Street on-ramp to

westbound I-90 would see an increase in the expected number of lane changes; however, the frequency should be negligible in terms of the overall safety impact on the corridor.

- **Eastbound I-90 from the HOV lane to either the 77th Street or Island Crest Way off-ramps (AM and PM peak hours):** Eastbound I-90 weaving volumes to the 77th Street off-ramp and Island Crest Way off-ramp would likely increase in comparison with the no-build condition. This is due to the fact that, under build conditions, HOV vehicles are required to weave across several lanes of traffic to access general-purpose Mercer Island off-ramps at 77th Street and Island Crest Way. Under no-build conditions, this weaving condition is less significant because HOV vehicles are able to use the eastbound center roadway to access Mercer Island.

Overall, the East Link Project would result in a lower number of lane changes, but this would be offset by a higher volume of mainline general-purpose vehicles than the no-build condition. Appendix H1, *Transportation Technical Report*, of this Final EIS further describes the qualitative safety review of the lane changes at the analyzed interchanges.

3.5.3.4 Construction Impacts

This section discusses potential impacts on I-90 and on other regional freeways. Appendix H1, *Transportation Technical Report*, of this Final EIS provides further information and data supporting the conclusions described in this section.

Interstate 90

The impacts due to construction of the light rail along I-90 were analyzed assuming a 2020 construction year. Before light rail is constructed on I-90, the I-90 Two-Way Transit and HOV Project would be completed and the reversible center roadway would be closed. As a result, all bus routes, HOVs, and Mercer Island drivers would be rerouted to the outer roadways. To construct East Link along I-90, the reversible center roadway and D2 Roadway would be affected. Constructing light rail tracks on these facilities would require their full closure. Buses that currently travel on the D2 Roadway would be detoured to adjacent I-90 accesses, either the SR 519/South Atlantic Street or Rainier Avenue South interchanges. While most construction activities would be on the reversible center roadway, activities might occur for the short term along the I-90 shoulder and outer roadway HOV lanes near the East Channel Bridge and Rainier Avenue South interchange.

The amount of automobile congestion on the outer roadways during the East Link construction period would be similar to East Link operations because the reversible center roadway would be removed in both of these conditions. Therefore, the vehicle travel times during the construction period would be similar to the travel times during East Link operations. Although the number of automobiles able to travel across Lake Washington on I-90 would be similar in both of these conditions, the auto demand to use the outer roadway would be greater in the construction period because light rail would not be operating. The person throughput would be less in the construction period than during East Link operations because the reversible center roadway would not be operational for vehicles or light rail; therefore fewer people would cross Lake Washington.

Compared to the No Build Alternative with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project completed, the SOV travel times in the construction period would generally be similar or better because the outer roadway HOV lanes would be constructed prior to the construction period. Vehicle throughput during the construction period compared to the No Build Alternative with only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project would be similar in the peak directions and higher in the reverse-peak directions because of the completion of the outer roadway HOV lanes. Person throughput, with the same comparison, would be less in the peak directions and higher in the reverse-peak directions.

Similar to the previous comparison, when East Link construction is compared with the No Build Alternative when all three stages of the I-90 Two-Way Transit and HOV Operations Project are completed, the SOV travel times would generally be similar or better during the construction period. One reason for this is the lower number of lane changes near the closed center roadway ramps creating less congestion. Person throughput in the reverse-peak directions (eastbound in the AM period and westbound in the PM period) at Screenline 2 (I-90 Floating Bridge) would be slightly higher during the East Link construction period than for the No Build Alternative when all three stages of the I-90 Two-Way Transit and HOV Project are completed. This is partly because the traffic analysis assumed Mercer Island drivers would be eligible to use the outer roadway HOV lanes when the center roadway is closed.

In the peak directions (westbound in the AM period and eastbound in the PM period), person throughput at Screenline 2 (Lake Washington) is expected to be higher in the No Build Alternative when all three stages of the I-90 Two-Way Transit and HOV Project are completed than in the East Link construction period as the center roadway and the outer roadway HOV lanes are open in this No Build Alternative. Although more people would cross Lake Washington in the No Build Alternative, during East Link construction the outer roadway HOV lanes would accommodate a substantial portion of the vehicles displaced from the center roadway as the center roadway is underutilized due to its connections not providing enough capacity to effectively use the two lanes in the center roadway.

At the I-90 and Bellevue Way interchange, the westbound mainline, HOV direct-access ramps, and ramps to and from I-90 to the east would experience short-term partial (likely nighttime) closures for construction of the elevated structures for the *Preferred Alternative B2M* or Alternatives B2A, B2E, B3, and B7. Alternative B1 would not require these closures because it would be at-grade underneath the mainline roadway. During periods when ramps are closed, vehicles would be detoured to the corresponding general-purpose or HOV ramp, but vehicles could also be detoured to another interchange.

Other Regional Freeways

Short-term impacts on I-405 and SR 520 are expected with the light rail construction. All Segment C alternatives would close multiple lanes of I-405, likely at night or on weekends depending on the construction method of the elevated structure over I-405, potentially causing drivers to detour and take alternative routes. I-405 impacts due to *Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C9A, and C14E would occur adjacent to the NE 6th Street direct-access ramps and NE 8th Street ramps to and from the south of NE 8th Street. Impacts associated with Alternatives C3T, C4A, C7E, and C8E would occur immediately north of the NE 12th Street overpass across I-405.

Along the SR 520 mainline, impacts would be limited to short-term shoulder or lane closures. SR 520 eastbound on- and off-ramps from 148th Avenue NE to West Lake Sammamish Parkway would experience shoulder or lane closures and temporary lane shifts for all Segment D and E alternatives, except Alternative D3 would not have any impacts to the 148th Avenue NE interchange, and when the elevated portions of Alternatives E1 and E4 cross SR 520 near the Lake Sammamish Parkway interchange and the elevated portion of Alternative E1 crosses SR 520 near the SR 202 interchange. These elevated crossings would result in each direction of SR 520 being closed at night, causing drivers to detour and take alternative routes. The westbound on-ramp and eastbound off-ramp at the SR 520 and SR 202 intersection would be reconstructed to provide clearance for the light rail structure that would be constructed for *Preferred Alternative E2* and Alternative E4.

3.5.4 Potential Mitigation

No mitigation would be necessary along the I-90 mainline during project operations because the project would have either similar or improved vehicle travel times and increased person throughput across Lake Washington in both the AM and PM peak periods compared to the No Build Alternative. In addition, before the East Link Project is constructed, the I-90 Two-Way Transit and HOV Project would be completed to provide HOV lanes on I-90 west to Seattle that replace the reversible center roadway used by East Link. During East Link construction, Sound Transit would coordinate with WSDOT on incident management, construction staging, and traffic control where the light rail construction may affect freeway traffic. Sound Transit would also coordinate with WSDOT to disseminate construction closure information to the public as needed.

For potential mitigation regarding transit on I-90, including mitigation for transit when the D2 Roadway is closed, refer to Section 3.4. For potential mitigation regarding freight on I-90, refer to Section 3.8. For potential intersection mitigation at or near I-90 ramp terminals, refer to Section 3.6.5.

3.6 Arterials and Local Streets

3.6.1 Methodology

This section describes the methodology applied to the analysis of existing conditions and environmental impacts on arterial and local street transportation elements, including roadway characteristics, intersection levels of service, safety, and parking.

3.6.1.1 Operations and Level of Service

Existing intersection vehicle movement counts were collected for the daily and AM and PM peak periods from local and state agencies (WSDOT, City of Seattle, City of Mercer Island, City of Bellevue, and City of Redmond). When study intersection count data were not available, new counts were acquired for the project. Additional information that was used in the intersection analysis included lane geometry, existing traffic signal timing, truck percentages, on-street parking, proximity to bus stops, and speed limits.

The quality of roadway traffic operations is described in terms of LOS. LOS grades range from LOS A to F, where LOS A represents the best operation (most vehicles do not stop at all) and LOS F represents the poorest operation (most of the drivers stop and will wait more than a minute until proceeding through the intersection). Traffic volumes were analyzed using *Highway Capacity Manual* methodology (Transportation Research Board [TRB], 2000), and LOS was calculated at signalized and unsignalized intersections. A more detailed discussion of the intersection analysis, results, and LOS descriptions is provided in the *Transportation Technical Report*.

3.6.1.2 Traffic Safety

Accident data for arterial intersections were collected from each jurisdiction and reviewed within the study area. Existing accident rates were calculated as the number of accidents per million entering vehicles (MEV). An assessment of the potential for accidents to occur with each alternative is provided based on existing accident patterns and how the East Link track profile aligns with roadway operations.

3.6.1.3 Parking

The analysis of parking supply and usage and of potential parking impacts from the East Link Project focused on areas with the greatest potential impact within an approximately 0.25-mile radius of stations. Parking supply and demand data were collected during spring 2007 for the area surrounding each proposed station. The survey included a space occupancy count, taken once during the morning and afternoon on a weekday. The time of the count was outside the peak periods to reflect longer-duration parking. The time periods selected represent "typical" conditions for parking demand based on the type of land use surrounding each station. Parking supply and demand were inventoried for two types of on-street parking: unrestricted and restricted. Restricted on-street parking includes all on-street parking that is restricted by meters, time limit signs, parking zones, or other restrictions.

3.6.2 Affected Environment

Because this Affected Environment (existing conditions) section was based on the year 2007, a few projects (such as some of the projects in the I-405 program, the NE 10th Street extension in Downtown Bellevue, and other minor intersection improvements) that have been constructed are included in the future no-build condition. Refer to the *Transportation Technical Report* for the list of these already completed projects.

3.6.2.1 Intersection Operations and Level of Service

Intersections were analyzed to understand whether they are operating acceptably or failing. Intersections are considered failing when they do not operate at or better than the agency's intersection LOS standard. Intersections that fail typically mean that vehicles incur substantial delay and queuing. Table 3-24 lists the LOS standards for each of the jurisdictions in the East Link study area. These standards were compared to the existing and future intersection LOS results to indicate when an intersection is operating acceptably or failing. The following subsections summarize existing LOS conditions in existing AM and PM peak hours at the study area intersections that were analyzed.

TABLE 3-24
Intersection Level of Service Standards

Jurisdiction	LOS Standard
Seattle	LOS D
WSDOT	LOS E
Mercer Island	LOS C
Bellevue: Segment B	LOS D
Bellevue: Segment C	LOS E
Bellevue: Segment D	LOS E
Redmond: Segments D and E	LOS E

Segment A

In Segment A, 11 intersections in Seattle and 20 intersections on Mercer Island were analyzed for existing AM and PM peak-hour conditions. Five of the intersections in Seattle and 13 of the intersections on Mercer Island are within WSDOT's jurisdiction because the intersection is at the ramp end or located near a ramp.

Six intersections in Segment A currently fail to meet the LOS standards in the existing condition: five in the PM peak hour and one in the AM peak hour. Out of all the intersections that fail, most operate at LOS E or F except for the 77th Avenue SE and North Mercer Way intersection on Mercer Island (LOS D in AM peak hour). Other failing intersections are at or near I-90 ramps: I-90 at 4th Avenue S in Seattle (western terminus of I-90) and East Mercer Way at the I-90 westbound off-ramp in the PM peak hour. The three other failing intersections in the PM peak hour are at S Dearborn Street and Rainier Avenue S, S Royal Brougham Way and 4th Avenue S, and 77th Avenue SE and SE 27th Street.

Segment B

In Segment B, 13 intersections in Bellevue and 6 intersections in WSDOT's jurisdiction were analyzed for existing PM peak-hour conditions. Four intersections—118th Avenue SE and SE 8th Street, 112th Avenue SE and SE 15th Street, Bellevue Way SE and SE 30th Street, and Bellevue Way SE and South Bellevue Park-and-Ride Lot—currently operate at LOS F in the PM peak hour. All four intersections are close to interstate facilities. All other intersections within Segment B meet the applicable intersection operation standard.

Segment C

In Segment C, 36 intersections in Bellevue and 7 intersections in WSDOT's jurisdiction were analyzed for PM peak-hour conditions. Of the 43 study intersections in Segment C, only the intersection at NE 8th Street at 112th Avenue NE operates at LOS F in the PM peak hour. Twelve intersections operate at LOS D or E, which indicates that these intersections are operating near or at capacity.

Segment D

In Segment D, 16 intersections in Bellevue and 12 intersections in Redmond were analyzed for PM peak-hour conditions. Of the 28 intersections studied in Segment D, 5 are in WSDOT's jurisdiction. None of the intersections in Segment D currently operate at LOS F. Three intersections along 148th Avenue NE operate at LOS E: SR 520 westbound ramp, NE 24th Street, and 20th Avenue NE. All other intersections operate at LOS D or better. Generally, the worst operating intersections are located along the highest-volume and most congested arterials: 140th Avenue NE, 148th Avenue NE, 20th Avenue, and 156th Avenue NE. An analysis of the AM peak hour along 156th Avenue NE and NE 40th Street was prepared because of the unique travel patterns created by the surrounding land uses. This analysis included five intersections and all those intersections met agency LOS standards.

Segment E

In Segment E, 22 intersections are in Redmond and 3 are in WSDOT's jurisdiction. The intersections of NE Leary Way and West Lake Sammamish Parkway, Avondale Road NE and NE Union Hill Road, and SR 202 and East Lake Sammamish Parkway operate at LOS F in the PM peak hour. The intersection of SR 202 and SR 520 westbound ramps operates at LOS E, while all other intersections in Segment E operate at or better than LOS D.

3.6.2.2 Traffic Safety

None of the study area intersections in Seattle have yearly accident totals higher than the City's standard 10 or more accidents per year at a signalized intersection and 5 or more accidents at an unsignalized intersection. Of the study intersections, the Rainier Avenue S and S Massachusetts Street intersection has the highest number of accidents, with seven accidents per year. The highest intersection accident rate on Mercer Island is at Island Crest Way and the I-90 eastbound off-ramp, with a rate of 0.75 accidents per MEV.

The intersection with the highest accident rate in Segment B is at 118th Avenue SE and SE 8th Street, with a rate of 0.27 accidents per MEV. In Segment C, two intersections have accident rates near or above 1.00 accident per MEV: 112th Avenue NE at NE 8th Street/I-405, and 110th Avenue NE at NE 10th Street. The highest accident rate in Segment D is at 130th Avenue NE and NE 20th Street, with an accident rate of 0.72 accidents per MEV. In Segment E, two intersections have intersection accidents rates over 1.00 accident per MEV: 164th Avenue NE and NE 76th Street and at 166th Avenue NE and SR 202, which have accident rates of 1.51 and 1.32 accidents per MEV, respectively.

3.6.2.3 Parking

Areas surrounding the proposed light rail stations have an on-street parking utilization rate of 88 percent or less, indicating that there is generally available on-street parking. Over half of the areas surrounding stations have a parking utilization of 50 percent or less.

Table 3-25 lists the existing unrestricted on-street parking utilization and supply information near the proposed stations. Restricted parking is not as likely to be used by light rail riders. Parking impacts identified due to the East Link Project primarily affect unrestricted parking near light rail stations, as discussed in the following Environmental Impacts section. In Segment A, 26 time-restricted on-street parking stalls with a utilization of 23 spaces were identified on Mercer Island. The parking survey on Mercer Island had the highest utilization rate in the study area at 68 percent. The parking located in the residential neighborhoods north of I-90 surrounding the Mercer Island Park-and-Ride Lot is restricted through a residential parking zone (RPZ) to reduce the impacts of park-and-ride spillover.

The Mercer Island Park-and-Ride Lot has approximately 450 parking spaces, of which 435 are currently used on the typical weekday (King County Metro, 2008b). On-street parking surrounding the Rainier Station site is unrestricted and has a utilization of approximately 40 percent.

Private parking garages in the Seattle neighborhoods serve most of the parking demand within Segment A. Much of the private parking surrounding the Rainier Station is located on commercial and light industrial properties along Rainier Avenue S. Private off-street parking garages are located throughout the Mercer Island Town Center, and private off-street parking is within moderate walking distance of the Mercer Island Station. Regulations for private parking are enforced by the private property owners at their discretion.

TABLE 3-25
Existing Unrestricted On-Street Parking Supply and Utilization by Station

Redmond Transit Center [b]	485	303	62	485	303	62

[a] Total on-street unrestricted parking.

[b] Restricted parking zones (RPZs) near the proposed stations have been implemented since the 2007 parking survey. These RPZs would reduce the available on-street unrestricted parking.

[c] Parking survey was conducted in spring of 2010 after initiation of Surrey Downs Residential Parking Zone.

Notes: Parking supply and demand data were collected in spring 2007 on all roads within a 0.25-mile radius of the stations.

Parking near the Mercer Island Station was collected in spring 2008 on all roads within a 0.25-mile radius of the station because the park-and-ride lot was closed during spring 2007.

In Segment B, on-street parking utilization rates were the lowest of any segment, with utilization rates around 10 percent. The on-street parking supply near the South Bellevue Station extended into the Enatai neighborhood, while most of the parking supply on 118th Avenue SE was east of I-405. No restricted on-street parking exists in any of the areas surrounding the stations in Segment B. The two park-and-ride lots in the South Bellevue segment, South Bellevue Park-and-Ride and the Wilburton Park-and-Ride, are both currently used at or near capacity on weekdays (King County Metro, 2007). People do not appear to be parking on-street in nearby neighborhoods and walking to these lots. Most off-street private parking within Segment B comprises parking lots surrounding office and commercial areas adjacent to SE 8th Street.

In Segment C, most on-street parking in Downtown Bellevue is restricted; therefore, the parking utilization rates were generally low, with the majority of the surveys calculating between 20 and 60 percent utilization. The on-street parking surrounding the Bellevue Transit Center had the highest utilization rate in Segment C, with percentages between 43 and 62 percent. There is no unrestricted on-street parking available in the areas around the Bellevue Transit Center and Ashwood/Hospital stations.

Private off-street parking within Segment C is located at major commercial and employment centers in Downtown Bellevue and the Ashwood/Hospital area. Hourly parking rates, monthly permits, and validation policies are typically enforced at private garages. Demand for private parking is highest in the day during traditional business hours.

All of the on-street parking surveyed in Segment D is considered unrestricted, with all of the surrounding areas near stations having parking utilization rates lower than 70 percent. The areas near the Overlake Village and Overlake Transit Center have the highest parking utilization rates (between 43 and 67 percent), but also have the lowest supply. The Overlake Village Park-and-Ride lot has 203 spaces, of which 33 percent are typically used each weekday. The Overlake Transit Center has 170 parking spaces, which are fully used each weekday (King County Metro, 2007). Within Segment D, the bulk of off-street parking occurs on private property throughout the Bel-Red Corridor in Bellevue and the Overlake area in Redmond.

In Segment E, parking utilization rates varied between 42 percent near the Redmond Town Center and Downtown Redmond Stations and 71 percent near the SE Redmond Station. Of the 377 parking spaces at the Redmond Transit Center, 80 percent are generally used each weekday. The Bear Creek Park- and-Ride lot, located about one mile east of the Redmond Transit Center, has 273 parking spaces, of which over 100 percent are used on a typical weekday (King County Metro, 2007). Private off-street parking is located at major employment and commercial centers within Segment E. Free parking is available at the Redmond Town Center.

3.6.3 Environmental Impacts

This section provides the future vehicular traffic and trips forecasted with each East Link station. Potential impacts on the arterial and local street operations (including property access and circulation patterns), traffic safety, and parking were assessed. A major component of the impact analysis for arterial and local street operations was the intersection LOS analysis for future years 2020 and 2030. A detailed discussion of the roadway and intersection impact analysis assumptions is presented in the *Transportation Technical Report*.

The intersection LOS analysis compared the 2020 and 2030 years for the East Link Project and the No Build Alternative in each segment study area. In general, the analysis predicted that, for light rail along at-grade profiles or elevated within the roadway right-of-way, intersections generally would operate at an LOS similar to that of the No Build Alternative, although a few intersections in the study area may degrade depending on the alternative and intersection movements. The similarity occurs partly because a similar roadway capacity is provided in most cases with East Link, but also because light rail trains, operating in at-grade profiles, are generally able to safely travel through intersections without substantial signal timing adjustments. At-grade alternatives outside of Downtown Bellevue would receive some level of priority at the traffic signals, although changes to the signal coordination are expected to be minimal because the traffic signals would have advanced detection of an approaching light rail train. Within Downtown Bellevue, at-grade alternatives would also likely receive some signal priority, but traffic signal coordination for autos would be maintained along key east-west arterials. For alternatives with either elevated or tunneled sections, intersections are expected to have operations similar to the No Build Alternative because these profiles are generally outside the roadway right-of-way.

Individual station impacts are described in each of the following segment discussions, but intersections near potential stations are expected to operate in most cases at an LOS similar to the No Build Alternative. Stations that include park-and-ride facilities are expected to generate more auto trips than other stations.

Therefore, at these locations, the intersections immediately adjacent to the stations may operate worse with the East Link Project than under the No Build Alternative because of the potential traffic increases at these intersections.

3.6.3.1 Traffic Forecasts and Station Trips

To evaluate impacts of the No Build Alternative and East Link Project on arterials and local streets, safety, and parking facilities, traffic was forecasted to determine the number of vehicles that would be on these facilities in the years 2020 and 2030. The analysis in this section uses the traffic forecasts presented in Section 3.3.3 and the ridership estimates presented in Section 3.4.3.6.

Overall, the annual traffic growth rate by year 2030 is expected to be between 1 and 2 percent per year within each segment for the No Build Alternative. With East Link, however, the study area is expected to experience slight changes in travel patterns as people adjust their mode of transportation and shift to light rail, thereby avoiding vehicle congestion and improving their travel times and trip reliability. This is further discussed in Section 3.3, Regional Travel. Additional information on the traffic forecasts is provided in the *Transportation Technical Report* in Appendix H1.

The number of person trips at each station was calculated based on the alternative that generates the highest PM peak-period (3-hour) ridership forecasts at that station. Included in this calculation is the number of park-and-ride and passenger drop-off and pick-up trips (also known as a kiss-and-ride trip) for each proposed East Link station. Additionally, PM peak bus service levels were provided by Metro and Sound Transit as part of the transit integration plan prepared for this project (Sound Transit, 2007). Year 2020 and 2030 daily, PM peak-period ridership and PM peak-hour vehicle trips for the highest ridership alternatives at each station are summarized by total auto and person trips in Table 3-26. Further information on the vehicle trip generation information associated with each station is provided in Appendix H1, Transportation Technical Report.

Within the study area, five of the proposed park-and-ride stations already exist as park-and-ride facilities. These are at Mercer Island, South Bellevue, Overlake Village, Overlake Transit Center, and Redmond Transit Center stations. With the project, the total number of parking stalls at the South Bellevue and Overlake Transit Center stations would increase. The 118th, 130th, and SE Redmond stations are proposed to be new park-and-ride facilities with this project. Instead of providing a park and ride at the 130th Station, this lot could be relocated to 120th Station with the *Preferred Alternative D2A*. The number of parking stalls at the Mercer Island, Overlake Village, and Redmond Transit Center stations would not be increased with this project. For the traffic analysis, all park-and-ride lots were assumed to be at full capacity, regardless of the vehicle demand from the ridership model. Section 3.6.3.4 identifies the existing and proposed parking stalls at park-and-ride stations and the number of autos expected to park there.

Kiss-and-ride trip: A vehicle trip where people drive to the station and drop off or pick up a passenger.

For the interim terminus ridership forecasts, three stations are predicted to have a noticeable increase in daily boardings: Hospital Station, Overlake Village Station, and Overlake Transit Center Station. These increases are largely due to the changes in bus service that would be planned to serve these stations if they are interim termini. Therefore, the increase in boardings is mainly due to people transferring to and from bus service, which would not be expected to have a noticeable impact on roadway operations.

In either year 2020 or 2030, the Hospital, Overlake Village, and Redmond Town Center stations are anticipated to have a noticeable increase in PM peak-hour vehicle trips, primarily due to an increase in kiss-and-ride trips. An additional traffic analysis has been conducted at these stations because of this increase in vehicle trips when they are an interim terminus. Table 3-27 provides daily PM peak-period ridership and PM peak-hour vehicle trips information at each potential interim terminus station.

3.6.3.2 Arterial and Local Street Operations

This section provides information by segment for arterial and local street operations. This includes impacts on intersection LOS and operations, traffic control, property access and circulation for the project alternatives, interim terminus stations, and maintenance facilities. Traffic safety on the arterial and local streets is addressed in Section 3.6.3.3, and parking impacts are discussed in Section 3.6.3.4. The *Transportation Technical Report* provides the complete list of roadway and intersection projects assumed in 2020 and 2030 in each project segment. Exhibits 3-20 through 3-26 illustrate year 2030 intersection operations with and without the project. For the year 2020 intersection exhibits, refer to the *Transportation Technical Report* in Appendix H1. Refer to the engineering drawings located in Appendix G1 for the proposed roadway channelization and traffic control for all alternatives.

[a] The daily station boardings provided in this table represent the highest ridership at that station from any East Link alternative.

[b] The PM peak-period (3-hour) park-and-ride forecasts shown are not constrained by the available parking supply.

[C] The PM peak-period (3-hour) person trips include all people boarding and alighting (exiting) bus and light rail.

[d] These peak-hour vehicle trips are the total number of new kiss-and-ride and park-and-ride trips associated with the East Link Project; these trips are incorporated in the traffic analysis. For bus volumes at each station refer to Section 6.3.1 of Appendix H1, Transportation Technical Report.

[e] C9T – East Main Station Design Option connecting from *Preferred Alternative B2M* would have no change in forecasts for either *Preferred Alternative C9T* or *B2M*.

[f] Instead of providing a park and ride at the 130th Station, this lot could be relocated to 120th Station with the *Preferred Alternative D2A*.

Note: Due to rounding, ridership might not sum exactly to totals.

Exhibit 3-26 **2030 PM No Build and Build Level of Service at Intersections Segment E**
East Link Project

Segment A, *Preferred Interstate 90 Alternative (A1)*

In Segment A, arterial and local streets are within the cities of Seattle and Mercer Island. With the No Build Alternative, local roadway access on Mercer Island to the I-90 outer roadway HOV lanes is provided by direct-access ramps as part of the I-90 Two-Way Transit and HOV Operations Project. No substantial arterial and local roadway improvements are considered in Segment A with the No Build Alternative.

Preferred Alternative A1 would convert the I-90 reversible center roadway for exclusive light rail use, as discussed in Section 3.5, while providing joint use by bus and light rail in the D2 Roadway. After converting the center roadway to light rail, the 77th Avenue SE and Island Crest Way reversible center roadway accesses would be eliminated and vehicles would use other I-90 access points. These access points could include the West Mercer Way, 76th Avenue SE, 77th Avenue SE, Island Crest Way, and East Mercer Way interchanges.

Additionally, as part of Stage 3 of the I-90 Two-Way Transit and HOV Operations Project, the current proposal to build the eastbound HOV off-ramp at 77th Avenue SE on Mercer Island is not the preferred design option in conjunction with the East Link Project, as bus use of the 77th Avenue SE ramp would be partially or wholly replaced by light rail service. Sound Transit, WSDOT, and the City of Mercer Island prefer to connect this access with the Island Crest Way eastbound off-ramp from the center roadway. A third design option that would construct neither of these eastbound off-ramp options is also considered. All three of these options were analyzed for impacts on the street system surrounding I-90 on Mercer Island.

Traffic Control, Property Access, and Circulation

Within Segment A, East Link is not expected to substantially affect traffic control, property access, or vehicular circulation on arterial streets because the *Preferred Alternative A1* and any of its design options are located on I-90 and do not travel along arterial or local street; however, circulation patterns are expected to change near the I-90 ramps on Mercer Island due to the closures of the reversible center roadway. Gates would be installed at the D2 Roadway ramps to ensure that general-purpose vehicles do not enter this facility.

If light rail operated exclusively in the D2 Roadway, then buses would need to modify their route and use another access location with I-90 (such as Rainier or SR 519 interchanges). This would not affect general vehicles and is discussed in more depth in Sections 3.4 and 3.5.

Operations and Level of Service

Throughout Segment A, the light rail profile is in an exclusive right-of-way separated from vehicle traffic, except in the D2 Roadway with joint bus and rail operations. Year 2030 intersection operations in Segment A for the No Build Alternative and East Link are depicted in Exhibits 3-20 and 3-21.

With East Link, the following intersections on Mercer Island (including the design option where the impact occurs) would not meet agency standards and operate worse than in the no-build condition:

- West Mercer Way and 24th Avenue SE (*Preferred Alternative A1* and both HOV off-ramp design options).
- 80th Avenue SE and SE 27th Street (*Preferred Alternative A1* and both HOV off-ramp design options)
- 77th Avenue SE and Sunset Highway (design option that provides a 77th HOV off-ramp)
- 77th Avenue SE and the I-90 eastbound HOV off-ramp (design option that provides a 77th HOV off-ramp)
- 77th Avenue SE and N Mercer Way (*Preferred Alternative A1* and both HOV off-ramp design options)
- 77th Avenue SE and I-90 eastbound off-ramp (Preferred Alternative A1 and design option that provides neither eastbound HOV off-ramp)
- 76th Avenue SE/N Mercer Way and I-90 westbound on-ramp (*Preferred Alternative A1* and both HOV off-ramp design options)

During the AM and PM peak hours, intersection operations in Seattle with East Link would vary only slightly when compared to the No Build Alternative. In the AM peak hour, intersection operations would generally stay the same or improve in Seattle, especially along Airport Way South and South Dearborn Street, because HOV access from the I-90 D2 Roadway would be restricted. HOVs would likely shift to the I-90 western terminus at South Atlantic Street/SR 519, which could lead to slightly worse intersection operations in this area.

During the PM peak hour, intersection operations in Seattle would vary slightly when comparing the East Link Project to the No Build Alternative. At the I-90 D2 Roadway terminus at 5th Avenue South and Airport Way South/South Dearborn Street, intersection operations again are expected to improve because the HOV access to the D2 Roadway would not be permitted. In the operational option to have exclusive light rail use in the D2 Roadway (i.e., bus services are not permitted), AM and PM peak-hour intersection operations would further improve at the D2 Roadway terminus and slightly degrade at the I-90 terminus on 4th Avenue.

On Mercer Island, some intersections that provide access to or are adjacent to I-90 in the build condition might experience some degradation in operations because of the changes in I-90 access between no-build and build conditions.

In *Preferred Alternative A1* (providing an eastbound HOV off-ramp at Island Crest Way) and the design option that does not provide any eastbound HOV off-ramp, all Mercer Island intersections would meet agency standards in the 2020 and 2030 AM peak hours. With the design option that would provide the eastbound 77th Avenue SE HOV off-ramp, the intersection of 77th Avenue SE and Sunset Highway would not meet agency standards in the 2020 and 2030 AM peak hours.

In the 2020 PM peak hour, the *Preferred Alternative A1* (eastbound HOV off-ramp to Island Crest Way) and the design option that provides neither eastbound HOV off-ramp, three intersections would not meet agency standards. These intersections are North Mercer Way and 77th Avenue SE, SE 24th Street and West Mercer Way, and SE 27th Street and 80th Avenue SE. These intersections are expected to operate at LOS D or E conditions. In addition, the I-90 eastbound off-ramp and 77th Avenue SE would exhibit vehicle queue lengths that extend onto the I-90 mainline. With the design option to provide a 77th Avenue SE HOV off-ramp, the intersection of 77th Avenue SE and I-90 eastbound HOV off-ramp would fail to meet agency standards in addition to those already identified above, except the I-90 eastbound off-ramp at 77th Avenue SE, which would not exhibit queues extending onto the I-90 mainline under this design option.

By 2030, the *Preferred Alternative A1* and the design option that provides neither eastbound HOV off-ramp, the 76th Avenue SE and I-90 westbound on-ramp intersection would fail to meet agency standards, in addition to those identified for the 2020 PM peak hour. With the design option to provide a 77th Avenue SE HOV off-ramp, the intersection of 77th Avenue SE and Sunset Highway would fail to meet agency standards in addition to those identified for the 2020 PM peak hour under this design option. Overall, by 2030, with the *Preferred Alternative A1* and the design option that does not provide any eastbound HOV off-ramp, five intersections would fail to meet agency standards, all in the PM peak hour. With the design option to provide a 77th Avenue SE HOV off-ramp, six intersections would fail to meet agency standards by 2030, five in the PM peak hour and one in both the AM and PM peak hours.

Segment B

With the No Build Alternative, the physical characteristics of the arterials and local roadways in 2020 and 2030 would remain the same as in existing conditions, except for modifications to the SE 8th Street interchange as part of the State's I-405 improvements.

With any Segment B alternative, roadway channelization generally remains similar to the No Build Alternative, except near the South Bellevue Station (described in the following section), as the alternatives are either outside the roadway right-of-way or, when the alternative is within the roadway, channelization is restored to no-build conditions.

Traffic Control, Property Access, and Circulation

Alternative B1 would have the highest number of traffic control revisions because it travels in the median along Bellevue Way SE, while Alternative B7 would have the fewest.

Preferred 112th SE Modified Alternative (B2M)

Preferred Alternative B2M (with either Segment C connection) would operate in exclusive right-of-way along the east side of Bellevue Way SE. Two roadway modification options are proposed to improve the station and neighborhood access along Bellevue Way near the South Bellevue Station. Of the two options, the second option, which does not install a traffic signal at SE 30th Street or provide a southbound HOV lane, is more consistent with the City of Bellevue's adopted long-range plans.

The first option would install two new traffic signals along Bellevue Way SE at the south driveway to the South Bellevue Station and at SE 30th Street and would convert the center two-way left-turn lane from the South Bellevue Station to I-90 into a southbound HOV lane. With the signal at the south driveway, westbound left turns exiting the South Bellevue Station would be allowed. Right-in/right-out access would be provided to residences south of the South Bellevue Station, and northbound and southbound U-turn movements would be allowed at the intersection of Bellevue Way SE, 112th Avenue SE, and the South Bellevue Station. At the SE 30th Street intersection, northbound traffic from I-90 would not be stopped by the signal. Access to the Sweylochen Boat Ramp would be right-in/right-out, and a northbound left turn into the Enatai neighborhood would be provided. The eastbound left turn exiting the Enatai neighborhood at SE 30th Street would be prohibited, and vehicles would be rerouted to 112th Avenue SE or another location.

The second option would also install a traffic signal at Bellevue Way SE and the south driveway to the South Bellevue Station. With this signal, northbound U-turn movements would be allowed at this intersection, and southbound U-turns would be allowed at the intersection of Bellevue Way SE, 112th Avenue SE, and the South Bellevue Station. No changes to property access and circulation along Bellevue Way would occur south of the south driveway, and the current movements allowed at SE 30th Street and Bellevue Way SE would remain.

For the connection to *Preferred Alternative C11A*, *Preferred Alternative B2M* along 112th Avenue SE would transition to at-grade center-running south of SE 15th Street, with the light rail train crossing of the northbound lanes controlled by gates. A signalized crossing would be provided at the SE 8th Street intersection. This variation of *Preferred Alternative B2M* would provide right-in/right-out access along 112th Avenue SE from Bellevue Way to SE 6th Street except at SE 8th Street, where left-turn and U-turn movements would be allowed. The pedestrian, bicycle, and maintenance driveways to Lincoln Plaza just south of SE 6th Street would be closed. Emergency access from south of the two driveways, however, would be maintained. Access to this property would be maintained on SE 6th Street, which would minimize the impact.

Along 112th Avenue SE, the connection from *Preferred Alternative B2M* to *Preferred Alternative C9T* would operate on the east side of 112th Avenue SE and cross SE 15th and SE 8th Streets as signalized gated crossings. A northbound right-turn pocket would be provided at the intersections of SE 8th Street and 112th Avenue SE and SE 15th Street and 112th. The emergency access driveway to Lincoln Plaza from 112th Avenue SE just south of SE 6th Street would be maintained, but the pedestrian, bicycle, and maintenance driveway would be closed. Access to this property is maintained on SE 6th Street, which would minimize the impact.

An option with the *Preferred Alternative B2M* connection to *Preferred Alternative C9T* would close the east approach at SE 15th Street to the Bellefield Office Park. Closing SE 15th Street would eliminate the conflict between light rail and vehicles, pedestrians, and bicyclists at this location. This closure would recirculate vehicles in the office park to the intersection of 114th Avenue SE and SE 8th Street. During emergencies, SE 15th Street might need to be opened, allowing for a secondary access into and out of the Bellefield Office Park.

Other Segment B Alternatives
For all alternatives, with the exception of Alternatives B1 and B7, traffic control, property access, and circulation near the South Bellevue Station to I-90 would be the same as described in *Preferred Alternative B2M.*

Alternative B1 would modify property access along Bellevue Way north of the 112th Avenue SE intersection and between the South Bellevue Station and I-90 to right-turn in/right-turn out because of the at-grade median profile. Between the 112th Avenue SE intersection and the South Bellevue Station an existing median is already in place, therefore, no change in property access would occur for this section. Where feasible, u-turn movements would be provided at signalized intersections along Bellevue Way to minimize circulation impacts.

South of the 112th Avenue SE intersection, Alternatives B2A, B3, and B3 - 114th Extension Design Option would have minimal impacts along Bellevue Way, similar to those of Alternative B1. North of this intersection, these three alternatives proceed along 112th Avenue SE until approximately SE 8th Street, restricting access to the Bellefield Office Park to the east and the residential properties to the west, allowing only right in/right-out movements. With the B3 – 114th Extension Design Option, an at-grade gated crossing of the northbound lanes on 112th Avenue SE, south of SE 8th Street, is provided.

Alternatives B2E and B7 would have minimal impacts on property access and/or traffic circulation because most of the length of these two alternatives would be either elevated or outside the roadway rights-of-way.

Operations and Level of Service
Year 2030 intersection operations in Segment B for the No Build Alternative and East Link are shown in Exhibit 3-22.

Under the No Build Alternative, intersection LOS in 2020 and 2030 is expected to degrade as traffic volumes increase on the roadways. Three intersections are expected to operate at LOS F in year 2020.

- SE 30th Street and Bellevue Way SE
- 112th Ave SE and SE 15th Street
- SE 8th Street and 118th Avenue SE

By 2030, the SE 6th Street and 114th Avenue SE and I-405 southbound ramps and Coal Creek Parkway intersections are also expected to operate at a failing LOS in the No Build Alternative.

The following intersections (including with the alternative where the impact occurs) would not meet agency standards with East Link and would operate worse than in the no-build condition.

- 112th Avenue SE and Bellevue Way SE (Alternatives B1, B2A, and B3)
- 112th Avenue SE/South Bellevue Station and Bellevue Way SE (Alternative B1)
- 112th Avenue SE and SE 15th Street (Alternatives B1, B2E, and B7)
- Coal Creek Parkway and I-405 southbound ramps (Alternative B7)
- 118th Avenue SE and SE 8th Street/I-405 southbound on-ramp (Alternative B7)

Preferred 112th SE Modified Alternative (B2M)
Under *Preferred Alternative B2M* with connections to *Preferred Alternatives C11A* or *C9T*, intersection operations would be similar to the no-build condition because of roadway and signal modifications along Bellevue Way SE and 112th Avenue SE.

The resulting intersection LOS along SE 8th Street at 112th Avenue SE and at 114th Avenue SE would still meet City of Bellevue LOS standards with the option to close the east approach at SE 15th Street to the Bellefield Office Park with the *Preferred Alternative B2M* connection to *Preferred Alternative C9T*. There would be, however, an increase in the northbound vehicle queues at the SE 8th Street and 114th Avenue SE intersection.

Other Segment B Alternatives
Alternatives B1, B2A, and B3 are at-grade throughout most of Segment B. These at-grade profiles would degrade intersection operations on Bellevue Way SE at the Bellevue Way SE and 112th Avenue SE intersection because of increased traffic associated with the expanded park-and-ride lot and changes in channelization due to the at-grade profile. Alternatives B2A and B3 are not expected to have any other intersection impacts. In addition to the proposed roadway modifications, under Alternative B1, pedestrians would access the light rail platform in one pedestrian crossing cycle, while pedestrians crossing Bellevue Way SE would require two pedestrian crossing cycles; this change in pedestrian crossing time would allow for improved intersection operations. No other intersections along Bellevue Way where light rail would operate at-grade are expected to experience worse intersection operations than in the no-build condition.

Because Alternative B2E is elevated throughout Segment B, intersection operations would not degrade due to route modifications. Only one intersection—112th Avenue SE and SE 15th Street—would degrade noticeably in this alternative. This effect is due to the increased traffic associated with the nearby stations.

The 118th Avenue SE and SE 8th Street intersection would operate at LOS F with the no-build condition and all Segment B alternatives. In Alternative B7, however, this intersection would operate with a higher delay than in the no-build condition due to the increased traffic from the new park-and-ride lot at the 118th Station. The intersection of Coal Creek Parkway and I-405 southbound ramps would also operate with a higher delay under Alternative B7 than in the no-build condition.

Segment C

Multiple projects are planned by the City of Bellevue and WSDOT within Segment C that will change the physical characteristics of major roadways from their existing condition, with or without the East Link Project, including the following:

- 110th Avenue NE widening from a three- and four-lane cross section to a five-lane cross section between NE 4th and NE 8th Streets
- NE 4th Street extension from 116th Avenue NE to 120th Avenue NE
- By 2030, NE 2nd Street widening from three lanes with on-street parking to five lanes between 112th Avenue NE and Bellevue Way NE

In general, Segment C tunnel alternatives (*Preferred Alternative C9T* and Alternatives C1T, C2T, and C3T) would not impact the roadway channelization except in some instances near the tunnel portals. At-grade alternatives within Segment C (*Preferred Alternative C11A* and Alternatives C4A and C9A) would require roadway modifications to 108th Avenue NE or 110th Avenue NE and NE 6th Street. Elevated alternatives in Segment C (Alternatives C7E, C8E, and C14E) would not impact roadway channelization except where the columns supporting the elevated structure are within the roadway right-of-way.

Traffic Control, Property Access, and Circulation
Alternative C4A would have the highest number of traffic control revisions because it travels at-grade along the side of 108th and 110th Avenues NE. The tunnel alternatives (Alternatives C1T, C2T, C3T, and C9T) and elevated alternatives along or east of 112th Avenue NE (C7E and C14E) would have the fewest revisions.

Preferred 108th NE At-Grade Alternative (C11A)

Preferred Alternative C11A has signalized crossings along 108th Avenue NE at Main, NE 2nd, NE 4th, and NE 6th Streets, a midblock pedestrian crossing north of NE 2nd Place, and signalized crossings at 112th Avenue SE and SE 6th Street and 110th Avenue NE and NE 6th Street. A southbound left-turn pocket would be provided at the 112th Avenue SE and SE 6th Street intersection. As *Preferred Alternative C11A* operates along portions of 108th Avenue NE and NE 6th Street in the median, property access and circulation is right-in/right-out except at signalized intersections, where all movements are allowed (including U-turn movements where appropriate) except the northbound left turns at NE 2nd Street and NE 4th Street. SE 4th Street would be closed to 112th Avenue SE. Access to SE 4th Street would be maintained via 111th Avenue SE. 110th Place SE and 110th Avenue SE would not have access to Main Street, but would have a new connection to one another. At Surrey Downs Park, the north driveway would be closed and the south driveway would allow right-in and right-out movements. No gates would be required. Due to the roadway realignment, the driveway may need to be rebuilt to the appropriate standards with this alternative.

With a connection to Alternatives B3, B3 - 114th Extension Design Option, or B7, no traffic control, property access, or circulation changes would occur along 112th Avenue SE because *Preferred Alternative C11A* would operate grade-separated east of 112th Avenue SE before transitioning to at-grade south of Main Street, west of 112th Avenue SE.

Preferred 110th NE Tunnel Alternative (C9T)

Preferred Alternative C9T has one signalized crossing at 112th Avenue SE and SE 6th Street. *Preferred Alternative C9T* would not affect roadway and property access and circulation except along 112th Avenue SE and NE 6th Street. SE 1st Street would be closed and not have access to 112th Avenue SE. Access to SE 1st Place would be maintained via 111th Avenue SE. SE 4th Street would be realigned to the intersection of 112th Avenue SE and SE 6th Street. With this realignment, northbound and southbound left turn pockets would be provided at SE 6th Street and 112th Avenue SE. Along NE 6th Street, property access would be similar to property access under *Preferred Alternative C11A*.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, *Preferred Alternative C9T* would operate in the same manner as *Preferred Alternative C11A* with no traffic control, property access, or circulation changes along 112th Avenue SE.

Other Segment C Alternatives

The tunnel alternatives (Alternatives C1T, C2T, and C3T) would have minimal traffic control, property access, and circulation impacts because they would mainly operate underground and would not affect vehicle circulation. Alternative C1T would restrict driveway access on Bellevue Way between the short section of SE 6th Street and SE Kilmarnock Street by allowing only right-in/right-out movements as it transitions to below grade; further, a new signal would be installed at the Bellevue Way SE and SE Kilmarnock Street intersection. Alternatives C2T and C3T would restrict driveway access on 112th Avenue SE south of SE 6th Street when connecting to Alternative B2A. All other Segment B connections to Alternatives C2T and C3T would not result in additional traffic control, property access, and circulation impacts on 112th Avenue SE. Alternatives C1T and C2T are similar to *Preferred Alternative C11A* once they exit their tunnel profiles east of the Bellevue Transit Station along NE 6th Street. Alternative C3T would require two road modifications north of NE 12th Street to serve the remaining residential properties. New connections to 110th Avenue NE would be constructed to the north and connect with 110th Avenue NE.

Alternative C4A would impact traffic circulation along 108th and 110th Avenues NE, and vehicles would operate one-way northbound along 108th Avenue NE and one-way southbound along 110th Avenue NE. Driveway locations on 108th and 110th Avenues NE where vehicles would cross light rail tracks would be potentially closed if access is available at another driveway location. The intersection at Main Street and 110th Avenue NE would be reconfigured to accommodate the realignment of 110th Avenue SE and 110th Place SE so that 110th Avenue south of Main Street would be realigned to match 110th Avenue NE north of Main Street. Minor impacts on traffic circulation at the NE 12th Street and 110th Avenue NE intersection are expected as a result of realigning 111th Avenue NE to connect to 110th Avenue NE. Private driveway access from existing properties on 111th Avenue NE would be maintained, and impacts on circulation would be expected to be minimal.

The Bellevue Transit Station location with Alternative C4A would close the City Hall visitor parking entrance on 110th Avenue NE; parking access would remain on NE 6th Street.

If Alternative C4A connects with Alternative B2A, there would be some property access and circulation impacts along 112th Avenue SE between SE 6th Street and just south of Main Street because the profile is at-grade and elevated in the median. Turning movements at driveways would be restricted to right-in/right-out movements. U-turn movements would be provided at the SE 6th Street and Main Street intersections along 112th Avenue NE to minimize circulation impacts. With the other Segment B connections, there would not be any traffic control, property access, or circulation impacts.

Alternative C7E is elevated along the east side of 112th Avenue NE, and its configuration would have minimal traffic control, property access, and circulation impacts. When connecting to Alternative B2A, traffic control, property access, and circulation along 112th Avenue SE between Main and SE 6th Streets would be similar to those under Alternative C4A. The signal at NE 6th Street and 112th Avenue NE also would be modified because of column placement. With the other Segment B connections, there would be no traffic control, property access, or circulation impacts.

Alternative C8E is expected to have some impacts on traffic control, property access, and circulation. Column placement along 110th Avenue NE between NE 2nd and NE 12th Streets would restrict turning movements to right-in/right-out at driveways. To minimize circulation impacts, U-turn movements at signalized intersections along this roadway section would be provided, where appropriate. Due to right-of-way constraints along 110th Avenue NE, northbound left turns at NE 8th Street would be prohibited and vehicles in this direction would have to turn left at either NE 4th or NE 10th Street. As this alternative only connects with Alternative B3, B3 - 114th Extension Design Option, or B7, traffic control, property access, or circulation would not be affected along 112th Avenue SE south of Main Street.

Alternative C9A, with a connection to Alternative B2A, would have traffic control, property access, and circulation impacts along 112th Avenue SE between Main and SE 6th Streets similar to those under Alternative C4A. A gated crossing would be provided to the properties south of Main Street at 110th Place SE. Alternative C9A would have signalized crossings along 110th Avenue NE at Main, NE 2nd, NE 4th, and NE 6th Streets. Because Alternative C9A would operate along 110th Avenue SE in the center median, property access and circulation would be right-in/right-out. This alternative would be similar to *Preferred Alternative C11A* once it becomes elevated on NE 6th Street. With the other Segment B connections, there would be no traffic control, property access, or circulation impacts.

Alternative C14E would have no signalized crossings or access and circulation impacts.

Operations and Level of Service

Year 2030 intersection operations with the No Build Alternative and East Link project are shown in Exhibits 3-23 and 3-24.

Under the No Build Alternative, intersections in Downtown Bellevue are expected to become more congested even as roadway projects are completed in the area. Four intersections in the study area are expected to operate at LOS F in 2020, and by the year 2030, four additional intersections are expected to operate at LOS F. These eight intersections are as follows:

- Bellevue Way and Main Street
- Bellevue Way and NE 4th Street
- Bellevue Way and NE 12th Street
- 112th Avenue NE and NE 8th Street (I-405 southbound off-ramp)
- 112th Avenue NE and Main Street
- 110th Avenue NE and NE 8th Street
- 112th Avenue NE and NE 12th Street
- 108th Avenue NE and NE 4th Street

With East Link, the majority of intersections in Segment C are expected to operate similarly to the No Build Alternative. This is due to the roadway modifications incorporated into each alternative and modified travel patterns related to a shift to transit. The following intersections (along with the alternative where the impact occurs) would not meet agency standards and would operate worse than in the no-build condition by 2030:

- Bellevue Way and Main Street (Alternative C1T)
- 112th Avenue NE and NE 12th Street (Alternatives C3T, C7E, and C8E)
- 112th Avenue NE and NE 8th Street (Alternatives C4A and C8E)
- 112th Avenue NE and Main Street (*Preferred Alternative C11A*)
- 110th Avenue NE and NE 8th Street (Alternatives C4A, C8E, and C9A)
- 110th Avenue NE and NE 6th Street (Alternative C9A)
- 108th Avenue NE and NE 12th Street (Alternative C4A)
- 108th Avenue NE and NE 4th Street (*Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C3T, C8E, and C9A)
- 108th Avenue NE and Main Street (*Preferred Alternative* C11A)

Preferred 108th NE At-Grade Alternative (C11A)

Most intersections in downtown Bellevue under *Preferred Alternative C11A* would operate similar to the No Build Alternative. The intersections of Main Street and 112th Avenue NE, Main Street and 108th Avenue NE, and NE 4th Street and 108th Avenue NE would not meet City of Bellevue LOS standards and would operate worse than the No Build Alternative. These impacts are due to roadway modifications and signal adjustments along 108th Avenue NE and because of passenger drop-off and pick-up traffic at the 108th Station and Bellevue Transit Center Station.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or Alternative B7, operations along 112th Avenue SE would be similar to a connection with *Preferred Alternative B2M*.

Preferred 110th NE Tunnel Alternative (C9T)

Most intersections in downtown Bellevue under the *Preferred Alternative C9T* would operate similar to the No Build Alternative because this alternative is mostly grade-separated from the street system. The intersection of NE 4th Street and 108th Avenue NE would not meet City intersection LOS standards and would operate slightly worse than the No Build Alternative condition with the additional drop-off/pick-up traffic at the Bellevue Transit Center Station.

A design option under *Preferred Alternative C9T* provides a Bellevue Transit Center Station exit and entrance on the west side of 110th Avenue NE. This would improve intersection operations at the intersection of 110th Avenue NE and NE 6th Street because the pedestrian-only signal phase would no longer be proposed to provide convenient pedestrian access to the station exit and entrance on the east side of 110th Avenue NE.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, operations along 112th Avenue SE would be similar to a connection with *Preferred Alternative B2M*.

Intersection LOS results for the East Main Street Station design option under *Preferred Alternative C9T* would be similar to a connection with Alternative B3, B3 - 114th Extension Design Option, or B7 that have an East Main Station.

Other Segment C Alternatives

Alternative C1T is grade-separated throughout most of Segment C except on Bellevue Way SE south of Kilmarnock Street, where the profile transitions from at-grade to a tunnel. The intersection operations at Bellevue Way and Main Street in both 2020 and 2030 are expected to get slightly worse from the traffic associated with the Old Bellevue Station. Overall, however, Alternative C1T is expected to cause little to no impact on the intersection LOS compared to the No Build Alternative.

Alternatives C2T and C3T are grade-separated throughout most of the Segment C. The intersection operations for both of these alternatives are expected to experience little change in LOS compared to the No Build Alternative except at the intersections of 108th Avenue NE and NE 4th Street under both alternatives and 112th Avenue NE and NE 12th Street under Alternative C3T. At both intersections, an increase in delay would result from additional trips associated with nearby stations.

The Alternative C4A is an at-grade profile throughout Segment C except south of Main Street when connecting to an elevated Segment B alternative. Alternative C4A operates as a light rail track couplet along 110th Avenue NE and 108th Avenue NE. Light rail would operate northbound along the east side of 110th Avenue NE and southbound along the west side of 108th Avenue NE between Main Street and NE 12th Street. Along 110th Avenue NE, to improve safety, auto traffic would be limited to the southbound direction with left-turn lanes at each intersection. Similarly, along 108th Avenue NE, auto traffic would be limited to the northbound direction with left-turn lanes at each intersection. Light rail gates are required at two intersections, at 111th Avenue NE north of NE 12th Street and at 110th Avenue SE south of Main Street, for the westbound light rail track.

Intersection operations with Alternative C4A are expected to experience some change compared to the No Build Alternative. Under Alternative C4A, three intersections would fail to meet standards and would operate worse than in the no-build condition: 108th Avenue NE and NE 12th Street, 110th Avenue NE and NE 8th Street, and 112th Avenue NE and NE 8th Street. These impacts would result from the changes in trip patterns and recirculation that would occur with a one-way couplet except at 108th Avenue NE and NE 12th Street, which is due to the at-grade light rail operations.

The 112th NE Elevated Alternative (C7E) is elevated throughout Segment C. With Alternative C7E, the Bellevue Transit Center Station would be located on 112th Avenue NE between NE 4th and NE 6th Streets. The resulting shift in passenger drop-off/pick-up traffic would not create additional delays at the intersections near this station. Intersection operations at 112th Avenue NE and NE 12th Street would fail to meet the intersection LOS standards due to additional trips associated with the Ashwood/Hospital Station.

Otherwise, this alternative is expected to cause little change in intersection LOS compared to the No Build Alternative.

Alternative C8E is elevated throughout Segment C. Along 110th Avenue NE between NE 2nd and NE 12th Streets, the number of lanes are reduced from a three- to five-lane section (planned by the City of Bellevue) for the No Build Alternative to a two- to four-lane section with the East Link Project. This is due to column placements and right-of-way constraints. The intersections of NE 8th Street at 110th Avenue NE, NE 8th Street at 112th Avenue NE, NE 12th Street at 112th Avenue NE, and 108th Avenue NE and NE 4th Street would operate at LOS F and worse than the no-build condition. This is a result of the shift in travel patterns associated with the reduction in travel lanes because of the median column placements and additional trips associated with the Bellevue Transit Center and Ashwood/Hospital stations. Otherwise, this alternative is expected to cause little change in intersection LOS compared to the No Build Alternative.

Under Alternative C9A, most intersections operate similar to the No Build Alternative. Along 112th Avenue SE, intersection impacts would be similar to those described for Alternative C4A. The intersections of NE 4th Street and 108th Avenue NE and NE 8th Street and 110th Avenue NE would not meet the City of Bellevue's intersection LOS standards and would operate worse than the No Build Alternative condition. Intersection delays along 110th Avenue NE would be higher with Alternative C9A than under the No Build Alternative, but would continue to operate within the City of Bellevue's LOS standards unless where noted.

Intersection operations with Alternative C14E would operate similar to the No Build Alternative condition due to the elevated alignment on the eastern edge of downtown Bellevue. If a parking garage were provided to support the Bellevue Transit Center Station with Alternative C14E, stalls would need to be managed to prohibit use by non-transit passengers. Also, congestion along NE 6th Street and 112th Avenue NE would likely become slightly worse and possibly require mitigation with the additional traffic associated with a parking garage.

With any of the nonpreferred Segment C alternatives, a connection to Alternative B3, B3 - 114th Extension Design Option, or B7 would not impact operations along 112th Avenue SE and intersection LOS results would be similar to the No Build Alternative.

With Alternatives C3T, C4A, C7E, and C8E, the gated crossing of 116th Avenue NE would be coordinated with the traffic signal at NE 12th Street and 116th Avenue NE to allow enough clearance for southbound vehicles potentially queued between NE 12th Street and the gated crossing. Intersection operations would meet City standards.

Concept Design Report Analysis

In addition to the analysis provided in this Final EIS, Sound Transit and the City of Bellevue cooperatively explored at-grade and grade-separated alternatives in Segment C and analyzed their effects on traffic operations using different models than those applied in this Final EIS. Results of the study are presented in the *Downtown Bellevue Light Rail Alternatives Concept Design Report* (CH2M HILL, 2010). A peer review of the study by traffic engineering and transit operations professionals from Seattle, Portland, Denver, and San Diego concluded that the traffic modeling, simulation, and operational analysis were sufficient to compare build alternatives. Based upon their experience in all four cities, the panel concluded that the surface alternatives studied would impact traffic operations in Bellevue similarly to those of the surface light rail systems in the comparable downtown environments of Portland, Denver, and San Diego. The panel noted that most changes in forecasted future traffic operating conditions in Downtown Bellevue would result from traffic volume growth and not from the introduction of surface light rail.

This analysis is not included in the Final EIS because the methodology is not consistent with the EIS approach reviewed by all cooperating agencies, a no-build condition was not analyzed, and some of the Segment C alternatives were not included. Even so, some of the key downtown traffic analysis findings are important to note. Specifically, two criteria (average vehicle delay for all downtown intersections and average vehicle delay for intersections adjacent to the at-grade light rail alignments) produced conclusions similar to those of the EIS analysis when comparing the grade-separated (*Preferred Alternative C9T* and Alternative C14E) and at-grade (Alternative C9A and *Preferred Alternative C11A*) alternatives. In both analyses, the difference between the grade-separated and the at-grade alternative for the average downtown vehicle delay was within 10 percent. The Final EIS analysis also projected percentage differences in vehicle delay for the key affected intersections similar to those presented in the *Downtown Bellevue Light Rail Alternatives Concept Design Report*.

Interim Terminus Stations

The Ashwood/Hospital and Hospital stations are potential interim termini. The ridership at the Ashwood/Hospital Station would not substantially increase as an interim terminus. The ridership at the Hospital Station would increase as an interim terminus. With a Hospital Station interim terminus, most additional ridership would result from transfers to and from buses. Therefore, no transportation impacts beyond what is described in the alternative route analysis would be expected.

Segment D

Within Segment D, multiple roadway projects planned by the cities of Bellevue and Redmond will change the physical characteristics of major roadways from their existing conditions, both with and without the East Link Project. Some of these planned roadway projects are:

- Extending NE 15th Street and NE 16th Street with widths varying between three and five lanes between 116th and 132nd Avenues NE
- Widening 120th and 124th Avenues NE to five lanes
- Widening 130th Avenue NE to provide a center two-way left-turn lane
- Widening Northup Way between 120th and 124th Avenues NE to accommodate an additional eastbound lane
- Implementing a multimodal pedestrian corridor along 152nd Avenue NE with one vehicle lane in each direction and left-turn lanes, bicycle lanes, parking and sidewalks

With any Segment D alternative, roadway channelization generally would remain similar to the No Build Alternative because the alternatives are either outside the roadway right-of-way or, when the alternative is within the roadway, the channelization is replaced.

Traffic Control, Property Access, and Circulation

Impacts on property access and circulation in Segment D are expected to affect mainly NE 16th Street, 136th Avenue NE, NE 20th Street, NE 24th Street, and 152nd Avenue NE. Substantial sections of the light rail track for each of the alternatives in Segment D would be outside the roadway right-of-way.

Preferred NE 16th At-Grade Alternative (D2A)

Preferred Alternative D2A would be located north of the planned NE 15th Street extension and would be grade-separated beneath 120th and 124th Avenues NE, with minimal impacts on property access and circulation in this area. *Preferred Alternative D2A* would then transition to at-grade center-running on NE 16th Street and 136th Place NE, with signalized crossings at 130th Avenue NE, 132nd Avenue NE, 136th Place NE, and NE 20th Street. Where *Preferred Alternative D2A* would operate center-running along NE 16th Street and 136th Place NE, property access and circulation would be right-in/right-out except at signalized intersections, where U-turn movements are provided.

The D2A - 120th Station Design Option associated with *Preferred Alternative D2A* includes a gated at-grade crossing at 120th Avenue NE, while the D2A - NE 24th Design Option includes a gated crossing at 151st Avenue NE and driveways along the west side of 152nd Avenue NE are closed. Access to these properties would be provided at the intersection of 151st Avenue NE and NE 24th Street. Two driveways on the north side of NE 24th Street would be closed, but vehicle access to these properties would remain at one driveway and at the NE 24th Street and 151st Avenue NE intersection. Because there are up to two remaining access locations along NE 24th Street, no substantial impacts would be anticipated.

Other Segment D Alternatives

Alternative D2E would travel outside the roadway right-of-way for most of the route length, and traffic control treatments would be minimal. At the intersections of 151st and 152nd Avenues NE and NE 24th Street, light rail crossings signals and gates would be provided. Driveway access on the south side of NE 24th Street between 148th Avenue NE and 151st Place NE would be removed to prevent vehicles from crossing the at-grade track. Internal circulation within properties would be modified to allow access via 148th Avenue NE and/or 151st Place NE. Similarly, driveways on the west side of 152nd Avenue NE between NE 24th and NE 28th Streets would be closed. Vehicle circulation within the surrounding office park would be routed to 151st Place NE.

Alternative D3 would have the most property access and circulation impacts because it would operate in the median along NE 16th and NE 20th Streets, prohibiting all midblock left-turn movements along these arterials between 120th Avenue NE and 136th Place NE along NE 16th Street, and between 136th Place NE and 152nd Avenue NE along NE 20th Street. Drivers would either be rerouted to the nearest signalized intersection to perform a U-turn movement, or they would adjust their travel patterns to use the surrounding street system. Signalized crossings would be provided along the NE 15th Street extension at 120th, 124th, 130th, and 132nd Avenues NE and at 136th Place NE. Signalized crossings would be provided along NE 20th Street at 140th Avenue NE and at the Ross Plaza entrance (14300 block). A signalized crossing would also be provided at the intersection of NE 24th and 152nd Avenue NE. North of NE 20th Street, Alternative D3 would proceed along 152nd Avenue NE as a median at-grade profile. This profile would prohibit midblock left-turn movements and potentially create U-turn movements at the signalized intersections of NE 24th and NE 26th Streets. Unlike Alternative D2E, the western property access along 152nd Avenue NE between NE 24th and NE 28th Streets would remain and allow right-in/right-out movements.

Alternative D5 would have the fewest property access and circulation impacts because most of the route is outside of arterial right-of-way. Similar to Alternative D2E, the driveways on the west side of 152nd Avenue NE between NE 26th and NE 28th Streets would be closed, and vehicle circulation would be routed to 151st Place NE.

For all Segment D alternatives, vehicle access to the park-and-ride at the Overlake Transit Center would be reconfigured to the NE 36th Street and 156th Avenue NE intersection.

Operations and Level of Service

Year 2030 intersection operations for the No Build Alternative and East Link are shown in Exhibit 3-25.

Intersection operations under the No Build Alternative in Segment D are expected to worsen as traffic volumes increase on the roadways. By year 2030, the following six intersections are expected to operate at LOS F:

- NE 20th Street and 140th Avenue NE
- NE 24th Street and 148th Avenue NE
- NE 24th Street and 152nd Avenue NE
- NE 40th Street and 156th Avenue NE
- NE 40th Street and 148th Avenue NE
- NE 36th Street and 156th Avenue NE

With East Link, the following intersections (including with the alternative where the impact occurs) would not meet agency standards and would operate worse than in the no-build condition:

- 120th Avenue NE and NE 16th Street (D2A – 120th Design Option, 2020 only)
- 148th Avenue NE and NE 20th Street (Alternative D3, year 2020 only)
- 151st Avenue NE and NE 24th Street (Alternative D2E)
- 152nd Avenue NE and NE 24th Street (*Preferred Alternative D2A*, D2A – NE 24th Design Option, Alternative D2E, and Alternative D5)

Preferred NE 16th At-Grade Alternative (D2A)

Intersection operations with *Preferred Alternative D2A* would operate similar to the No Build Alternative because this alternative would be either grade-separated from the roadway or, when at-grade, it generally would operate parallel to the major traffic movements and the number of roadway lanes provided would remain the same as the No Build Alternative.

With the D2A - 120th Station Design Option, the intersection of NE 15th Street and 120th Avenue NE would not meet City intersection LOS standards and would operate worse than the No Build Alternative condition in year 2020. By year 2030, the intersection would meet City LOS standards as a result of planned City of Bellevue improvements along 120th Avenue NE.

Although the *Preferred Alternative D2A* and the D2A - NE 24th Design Option would not cross the intersection of NE 24th Street and 152nd Avenue NE, this intersection would not meet City of Redmond intersection LOS standards because of additional trips associated with the Overlake Village Station. The intersection of NE 24th Street and 151st Avenue NE would also not meet City intersection LOS standards because of driveway closures along the west side of 152nd Avenue NE and train operations associated with the D2A - NE 24th Design Option.

With the *Preferred Alternative D2A* there is the potential to locate the park-and-ride lot at either the 130th Station or 120th Station. With either location, traffic operations, including the number of intersections failing to meet the intersection LOS standards, would be similar to the previously described analysis for the *Preferred Alternative D2A*.

Other Segment D Alternatives

Because Alternative D2E generally shares the same route as *Preferred Alternative D2A*, the intersection results are similar. Intersection operations would degrade at the intersections of NE 24th Street and 151st Avenue NE and NE 24th Street and 152nd Avenue NE due to signal adjustments necessary for safe operation of light rail as it transitions from the south side of NE 24th Street to the west side of 152nd Avenue NE.

Alternative D3 would be at-grade or in a trench throughout most of Segment D. Along 152nd Avenue NE, Alternative D3 would operate at-grade in the median until it becomes aligned with the west side of the road north of Microsoft Road. By operating in the median on 152nd Avenue NE, light rail trains would be able to travel with the north-south through traffic, minimizing impacts at NE 24th Street and 152nd Avenue NE intersection. Otherwise, there would be little difference in intersection operations from the No Build Alternative.

Because Alternative D5 would be primarily elevated or within SR 520 right-of-way, there would be little difference in intersection operations from the No Build Alternative except at NE 24th Street and 152nd Avenue NE, where additional trips from the nearby Overlake Village Station would cause an increase in delay compared to the no-build condition.

Under any Segment D alternative, AM peak hour intersection operations along 156th Avenue NE and NE 40th Street would vary only slightly when compared to the no-build condition. In 2030, no intersections would fail to meet intersection operating standards in the build condition and none would operate worse than the no-build condition.

Interim Terminus Stations

The 120th, 130th, Overlake Village, and Overlake Transit Center Stations are potential interim termini. Even though ridership at these interim termini stations would increase by up to 1,500 (Table 3-27), only the Overlake Village Station warranted further traffic impact analysis. This additional ridership at the Overlake Village Station would be largely comprised of people using bus service; therefore, bus services would be increased to accommodate this additional ridership. This increase in bus service would have minimal impact on vehicle operations. Therefore, no change in intersection LOS is expected. The increase in bus service at the Overlake Village Station would be mainly with routes to and from the north along 156th Avenue NE.

Segment E

In Downtown Redmond, Cleveland Street and Redmond Way currently operate as a one-way couplet with traffic operating eastbound and westbound, respectively. In the future no-build condition, these two streets are planned to be converted to two-way operations, with Redmond Way providing one through lane and one left-turn pocket in both directions at intersections and Cleveland Street providing one lane in each direction. In addition, right-turn pockets will be provided for the eastbound and westbound approach at the intersection of Redmond Way and 164th Avenue NE. 164th Avenue NE will be extended between NE 76th Street and Cleveland Street. Bear Creek Parkway and 161st Avenue NE will also be extended to intersect south of the former BNSF Railway right-of-way.

With any Segment E alternative, roadway channelization generally remains similar to the No Build Alternative, as the alternatives are either outside the roadway right-of-way or when the alternative is within the roadway the channelization is replaced.

Traffic Control, Property Access, and Circulation

The alternatives in Segment E follow a general route that parallels SR 520 for a large portion of the segment length and use a substantial portion of existing former BNSF Railway right-of-way parallel to NE Redmond Way, so property access and circulation issues would generally be minimal.

Preferred Marymoor Alternative (E2)

For *Preferred Alternative E2,* light rail crossing gates would replace the existing railroad gates and serve as traffic controls along the former BNSF Railway corridor (at the 161st Avenue NE, Leary Way, 164th Avenue NE, 166th Avenue NE, and 170th Avenue NE crossings). *Preferred Alternative E2* would not affect the roadway channelization along the Segment E roadways. There would be no property access or circulation impacts with the *Preferred Alternative E2*.

The E2 – Redmond Transit Center Design Option would extend from *Preferred Alternative E2* and into Downtown Redmond along 161st Avenue NE between Cleveland and NE 85th Streets. The E2 – Redmond Transit Center Design Option would have more impacts on property access and circulation than *Preferred Alternative E2* because this design option would be at-grade in the median of 161st Avenue NE, restricting midblock property access to only right-in and right-out movements. To minimize vehicle recirculation, NE 83rd Street and 161st Avenue NE would be signalized, and U-turn movements would be allowed at the intersection of NE 85th Street and 161st Avenue NE.

Other Segment E Alternatives

With Alternative E1, properties with access on the south side of Redmond Way near the 159th Place NE intersection might have their access altered to accommodate the light rail track. West Lake Sammamish Parkway and the former BNSF Railway right-of-way would be modified to accommodate the tracks along the road. With Alternative E4, access to a residential property along the south side of Leary Way, just west of the Sammamish River, could potentially be modified to accommodate the light rail tracks along the road. Similar to *Preferred Alternative E2*, both Alternatives E1 and E4 would have light rail crossing gates along the former BNSF Railway corridor (at the 164th Avenue NE, 166th Avenue NE, and 170th Avenue NE crossings). Alternative E1 would have additional crossings at 161st Avenue NE and NE Leary Way, while Alternative E4 would have additional crossings at the intersection of Bear Creek Parkway and NE Leary Way and along NE 76th Street between NE Leary Way and 164th Avenue NE.

A service access road would be constructed near the SR 520 eastbound on-ramp and West Lake Sammamish Parkway to allow access to a traction power substation. However, this access point would be used by service vehicles only, and it would not likely affect circulation or property access near the on-ramp.

Traffic control and circulation along the former BNSF Railway corridor would be the same under all Segment E alternatives.

Operations and Level of Service

Year 2030 intersection operations in Segment E for the No Build Alternative and East Link are shown in Exhibit 3-26. As traffic volumes increase in 2020 and 2030, the intersection LOS results for the No Build Alternative would worsen from existing conditions. In the year 2020, three intersections are expected to operate at LOS F. By year 2030, two additional intersections for a total of five intersections are expected to operate at LOS F:

- NE Leary Way and West lake Sammamish Parkway
- NE 76th Street and 170th Avenue NE
- Avondale Road NE and Union Hill Road
- SR 202 and East Lake Sammamish Parkway (180th Avenue NE)
- NE 85th Street and 164th Avenue NE

With East Link, the following intersections (including the alternative where the impact occurs) would not meet agency standards and would operate worse than in the no-build condition in both 2020 and 2030:

- NE 76th Street and 170th Avenue NE (all Segment E alternatives)
- SR 202 and East Lake Sammamish (all Segment E alternatives)
- NE 70th Street and 176th Avenue NE (*Preferred Alternative E2* and E2 – Redmond Transit Center Design Option)

With East Link, the following intersections (including the alternative where the impact occurs) would not meet agency standards and would operate worse than in the no-build condition in year 2030 only:

- Redmond Way and 161st Avenue NE (E2 – Redmond Transit Center Design Option)
- SR 202 and NE 70th Street (all Segment E alternatives)

Preferred Marymoor Alternative (E2)

Intersection operations with the *Preferred Alternative E2* would be similar to the no-build condition except at the following four intersections where operations are expected to be worse and fail to meet City LOS standards: NE 76th Street and 170th Avenue NE, SR 202 and NE 70th Street, NE 70th Street and 176th Avenue NE, and SR 202 and East Lake Sammamish Parkway (180th Avenue NE). These impacts are due to the increase in traffic associated with the SE Redmond Station and the at-grade light rail crossing adjacent to the NE 76th Street and 170th Avenue NE intersection.

For the E2 – Redmond Transit Center Design Option, the intersection operations would be similar to those of *Preferred Alternative E2*, except at the Redmond Way and 161st Avenue NE intersection. This intersection is expected to operate at LOS F in 2030 because of roadway modifications along 161st Avenue NE to accommodate the median track alignment.

Independent of the *Preferred Alternative E2* alignment adjacent to NE 76th Street, the intersection signal phasing and operations along NE 76th Street would be similar as discussed under the *Preferred Alternative E2* and E2 – Redmond Transit Center Design Option.

Other Segment E Alternatives

With Alternative E1, intersection operations in year 2020 would be similar to the No Build Alternative except at the intersections of NE 76th Street at 170th Avenue NE and SR 202 at East Lake Sammamish Parkway. These two intersections would fail to meet intersection LOS standards. In year 2030, intersection operations would be similar to the No Build Alternative except at the two already identified as failing in year 2020 and at the intersection of SR 202 at NE 70th Street, which would fail to meet intersection LOS standards. These impacts are due to the increase in traffic associated with the SE Redmond Station and the at-grade light rail crossing adjacent to the NE 76th Street and 170th Avenue NE intersection.

Year 2020 and 2030 intersection operations with Alternative E4 would be similar to those of Alternative E1.

Interim Terminus Stations

The SE Redmond and Redmond Town Center stations are potential interim termini. The SE Redmond Station is not expected to generate enough automobile trips beyond the full-length alternative to warrant further traffic analysis because the full-length analysis assumed the SE Redmond Park–and-Ride will be at capacity. From Table 3-27, only the Redmond Town Center Station would generate enough additional PM peak-hour vehicles trips as an interim terminus to warrant further traffic analysis. Intersections near the Redmond Town Center Station are expected to meet City of Redmond LOS standards in the future except the intersection of NE 76th Street and 170th Avenue

NE. The increase in delay at this intersection is attributed to the at-grade light rail crossing adjacent to the intersection, similar to all Segment E Alternatives.

Maintenance Facilities

The potential maintenance facility sites in segments D and E are not expected to adversely affect intersection operations, property access, or traffic circulation. The *Transportation Technical Report* provides a detailed discussion of the traffic circulation at each of these potential maintenance facilities.

All maintenance facility alternatives would have approximately 60 parking stalls for employees and visitors. Maintenance facility staff shift hours would be similar to Central Link operation and maintenance facilities—6:00 a.m. to 2:00 p.m. and 2:00 p.m. to 10:00 p.m. These shift hours occur outside the peak periods, so little shift traffic is expected to occur during the peak hour. Fewer than 10 vehicle trips would occur to and from the maintenance facilities during the peak periods. These trips would include visitors and deliveries to and from the maintenance facilities.

Light rail vehicle storage track would be located along the former BNSF Railway right-of-way within Segment D. Light rail vehicles entering or exiting this vehicle storage track would have no impact on traffic operations as this activity would occur outside of vehicle roadways. Parking and limited office space for vehicle maintenance, such as cleaning, would occur at this location, but no impacts on traffic operations are anticipated.

3.6.3.3 Traffic Safety

This section provides a safety impact assessment of each alternative. The safety impact assessments are based upon *Integration of Light Rail Transit into City Streets* (Korve et al., 1996) and *Light Rail Service, Vehicular and Pedestrian Safety* (TRB, 1999). The *Transportation Technical Report* provides further discussion of safety impacts.

No substantial change from the existing accident conditions is expected with the No Build Alternative in any segment. Overall, the project-generated trips created by the East Link alternatives are not expected to increase the accident rates for automobiles because the roadway conditions would remain similar to or improve compared to the No Build Alternative.

Many of the at-grade alternatives (*Preferred Alternatives B2M* [when connecting to *Preferred Alternative C11A*], *C11A*, and *D2A* and Alternatives B1, B2A, B3, C9A, and E2 – Redmond Transit Center Design Option) would operate in the roadway median for some portion along the route and resemble the current light rail train operations along the 4-mile track in the center median of Martin Luther King Jr. Way in Seattle. During the first year of revenue service of the Central Link system (July 2009 through June 2010), seven light rail train and vehicle accidents and one light rail train and pedestrian accident occurred, and overall corridor accidents per year decreased from 327 (before light rail) to 134 (after light rail). The light rail train accidents constitute about 6 percent of the total number of accidents along the corridor, and the corridor total was reduced by close to 60 percent once the light rail train revenue service began. The light rail train median barrier, which restricts vehicle turns to signalized intersections, is considered one of the contributing factors in the overall accident reduction along the corridor. Additionally, none of the light rail train-related accidents were considered life-threatening, and all of the light rail train-vehicle accidents involved vehicles illegally turning.

Segment A, *Preferred Interstate Alternative (A1)*

The proposed alternatives in Segment A consist of an at-grade profile located on I-90. Impacts on traffic safety on arterial and local streets are not expected because the proposed alternative would not operate on or require any right-of-way from local streets in the city of Seattle or the city of Mercer Island.

Segment B

Preferred 112th SE Modified Alternative (B2M)

The *Preferred Alternative B2M* when connecting to *Preferred Alternative C11A* would operate at-grade in the median along 112th Avenue SE, which would have a greater potential for vehicle-train accidents at roadway crossings than routes outside the roadway right-of-way. At-grade crossings occur south of SE 15th Street and at SE 8th Street. However, potential safety benefits related to eliminating midblock turning movements could reduce the overall accident rate. The *Preferred Alternative B2M* when connecting to *Preferred Alternative C9T* would operate at-grade and side-aligned, with crossings at SE 15th Street and SE 8th Street. An option to close the minor approach at SE 15th Street would result in only one crossing at SE 8th Street under *Preferred Alternative B2M* when connecting to *Preferred Alternative C9T.*

Other Segment B Alternatives

Alternatives B7 and B2E are expected to have minimal or no impact on the number of accidents because the light rail profile is separate from other travel modes. Alternatives B2A and B3 have some at-grade median sections with similar safety characteristics and numbers of crossings to the *Preferred Alternative B2M* with a connection to *Preferred Alternative C11A*. Alternative B1 has the greatest length of median at-grade design with seven crossings along Bellevue Way, but there would be the potential for an overall decrease in the accident rate through the elimination of mid-block turning accidents and protecting all left-turn movements on Bellevue Way, similar to the accident experience with Central Link along Martin Luther King Jr. Way in Seattle.

Segment C

Preferred 108th NE At-Grade Alternative (C11A)

The *Preferred Alternative C11A* would operate at-grade in the median along a portion of 112th Avenue SE, 108th Avenue NE, and NE 6th Street, with crossings at SE 6th Street, Main Street, NE 2nd Street, NE 4th Street, NE 6th Street, and 110th Avenue NE. These crossings would have a greater potential for vehicle-train accidents than routes outside the roadway right-of-way. However, potential safety benefits related to eliminating midblock turning movements could reduce the overall accident rate similar to the Central Link accident experience along Martin Luther King Jr. Way.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, no impact on accidents along 112th Avenue SE would be expected because the light rail profile would be grade-separated.

Preferred 110th NE Tunnel Alternative (C9T)

The *Preferred Alternative C9T* operates at-grade and side-aligned, with one signalized crossing along 112th Avenue SE, and grade-separated elsewhere in Segment C. At this crossing the train would operate in its own signal phase, so no substantial change in the number of accidents is expected.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, no effect on accidents along 112th Avenue SE would be expected because the light rail profile would be grade-separated.

Other Segment C Alternatives

Alternative C4A operates at-grade along 108th Avenue NE and 110th Avenue NE with crossings at Main, NE 2nd, NE 4th, NE 6th, NE 8th, NE 10th, and NE 12th Streets. These crossings would have a greater potential for vehicle-train accidents than routes outside the roadway right-of-way, but the design minimizes the interaction between at-grade light rail trains and vehicles. Converting both 108th and 110th Avenues NE to one-way vehicle streets, in the opposite direction of the light rail train, would reduce the number of movements that cross the light rail tracks and allow drivers to see approaching trains. Business driveways that cross the light rail track would potentially be closed if an alternate access to the business is available.

Alternatives C1T, C2T, C3T, C7E, C8E, and C14E are either tunnel or elevated alternatives mainly outside the roadway right-of-way. The biggest safety issue expected would be column placement in side-aligned elevated sections to avoid blocking driver visibility at intersections and driveways. For elevated sections in medians, column placement is not expected to create driver visibility issues because left turns between the columns would be prohibited and left turns at intersections would be controlled by traffic signals.

For alternatives with a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, no impact on accidents along 112th Avenue SE would be expected because the light rail profile would be grade-separated. For alternatives with a connection to Alternative B2A, operations would be median at-grade for a short distance and then transition to side-aligned elevated, and would have a similar accident experience as Central Link along Martin Luther King Jr. Way.

Alternative C9A would have safety characteristics along 110th Avenue NE similar to the P*referred Alternative C11A* along 108th Avenue NE.

Segment D

Preferred NE 16th At-Grade Alternative (D2A)

The *Preferred Alternative D2A* would operate primarily grade-separated or outside the roadway, but it has some sections of at-grade median operations along NE 16th Street and 136th Place NE with crossings at 130th Avenue NE, 132nd Avenue NE, NE 16th Street, and NE 20th Street. These at-grade median sections would have a greater potential for vehicle-train accidents than routes outside the roadway right-of-way. However, potential safety benefits related to the elimination of midblock turning movements could reduce the overall accident rate similar to the Central Link accident experience along Martin Luther King Jr. Way.

The D2A – 120th Station and NE 24th design options would have safety characteristics similar to *Preferred Alternative D2A* except with the one additional at-grade gated crossing in each design option.

Other Segment D Alternatives

Alternatives D2E and D5 would mostly operate outside of the roadway right-of-way; consequently, no substantial changes are expected in the accident frequency. In the elevated sections of Alternative D2E, columns would be placed so that driver visibility at driveways and intersections would not be obstructed. The at-grade crossing of 151st Avenue NE and 152nd Avenue NE would be gated and signalized for Alternative D2E.

Alternative D3 includes segments within the roadway right-of-way. Alternative D3 operates in the median on NE 16th Street, 136th Place NE, and 152nd Avenue NE with crossings at 120th, 124th, 130th, 132nd, and 140th

Avenues NE; NE 16th and NE 20th Streets; and the 14300 block (Ross Plaza) of NE 20th Street. These at-grade median sections would have a greater potential for vehicle-train accidents than routes outside the roadway right-of-way. However, potential safety benefits related to eliminating midblock turning movements could reduce the overall accident rate similar to the accident experience along Martin Luther King Jr., Way. Alternative D3 also operates in a retained cut on NE 20th Street and 152nd Avenue NE. Some at-grade crossings would also be gated. Providing traffic signals and/or gates at crossings minimizes the risk of increasing the accident frequency.

Segment E

Preferred Marymoor Alternative (E2)

Preferred Alternative E2 would mostly operate outside roadway right-of-way, and combined with the use of gated crossings, the risk of increasing the accident frequency would be minimal. Therefore, no substantial change in the number of accidents is expected. At-grade crossings would occur at 170th, 166th, 164th, and 161st Avenues NE and Leary Way NE.

Under the E2 – Redmond Transit Center Design Option, a portion of the alternative would be within the 161st Avenue NE right-of-way. Even so, the accident frequency is not expected to substantially change. Any accidents that occur in this median at-grade section would likely be relatively minor due to the low speed of the light rail train as it is entering and exiting the station. Additional at-grade crossings with this design option would occur at Redmond Way NE; and Cleveland, NE 83rd, and NE 85th Streets.

Other Segment E Alternatives

The Redmond Way (E1) and Leary Way (E4) Alternatives would have the same safety characteristics as *Preferred Alternative E2.*

Maintenance Facilities

No substantial changes are expected in the accident frequency along the roadways surrounding the maintenance facilities. Two maintenance facilities would have track crossing roadways: Maintenance Facility 3 (MF3), where track would spur off the main light rail track and cross NE 20th Street, and the SE Redmond Maintenance Facility (MF5), where track would cross NE 70th Street. Light rail trains would not cross these roads frequently and they would be protected with gates, so there would be no expected change in roadway safety conditions.

3.6.3.4 Parking

This section describes the key impacts on parking due to light rail within each segment, including on- and off-street parking removal and the potential for hide-and-ride and spillover parking impacts. Section 3.6.5 discusses possible parking mitigation strategies to reduce the hide-and-ride potential. Table 3-28 lists the parking impacts from each alternative. These are briefly discussed in the following subsections. This parking assessment is based on the current level of design completed for each alternative. In subsequent design refinements, the on- and off-street parking impacts may be adjusted. Parking impacts for each alternative are discussed in further detail in the *Transportation Technical Report* (Appendix H1). Table 3-29 lists the existing and proposed park-and-ride stalls and the forecasted PM peak-period (3-hour) vehicle usage at station park-and-ride facilities for years 2020 and 2030.

Spillover Parking. Transit riders that park on-street near park-and-ride lots due to the lot being full.

Hide-and-Ride Parking. Transit riders who park on-street near a transit stop and board transit.

Segment A, *Preferred Interstate 90 Alternative (A1)*

There would be no direct on-street or off-street parking impacts associated with the *Preferred Alternative A1* or any of the design options in Segment A. The potential for hide-and-ride parking impacts at the Rainier Station is expected to be high because there is a substantial amount of surrounding on-street parking available to accommodate riders. At the Mercer Island Station, there is a low potential for impacts with alternatives that include the South Bellevue Station (*Preferred Alternative B2M* and Alternatives B1, B2A, B2E, and B3). The location of the South Bellevue Station, which is proposed to provide over 1,400 stalls, provides riders with a higher-parking capacity option for drivers along I-90. In addition, although the current demand for the Mercer Island Park-and-Ride is near its parking capacity, there is minimal parking spillover into the surrounding areas due to the restricted parking, which indicates that the future level for hide-and-ride impacts is low.

For Alternative B7, there could be a slightly greater potential for spillover parking at the Mercer Island Station because the forecasted auto usage is higher than the Mercer Island Park-and-Ride capacity. Because the current park-and-ride lot is almost fully utilized and this alternative does not include a nearby light rail station with a park-and-ride lot, there might be a potential for parking spillover in the unoccupied on-street parking spaces (see Table 3-25). However, the City of Mercer Island recently implemented restricted (time-limited) parking in selected areas surrounding the Town Center, and those restrictions combined with the enforced RPZs in the residential neighborhoods north of I-90 would limit hide-and-ride parking at the Mercer Island Station.

TABLE 3-28
Parking Impacts by Alternative

Alternative	Parking Spaces Removed	
	On-Street	**Off-Street**[e]
Segment A		
Preferred Alternative A1	0	0
Segment B		
Preferred Alternative B2M to *Preferred Alternative C11A*	0	20
Preferred Alternative B2M to *Preferred Alternative C9T*	0	20
Alternative B1	0	57
Alternative B2A	0	7
Alternative B2E	0	18
Alternative B3	0	3
B3 - 114th Extension Design Option	0	73
Alternative B7	0	18
Segment C[a,b]		
Preferred Alternative C11A	10	340 to 360
Preferred Alternative C9T[c]	0	385 to 410
Alternative C1T	0	158
Alternative C2T	0	82 to 172
Alternative C3T	0	26 to 106
Alternative C4A	11	39 to 94
Alternative C7E	0	198 to 226
Alternative C8E	0	92 to 125
Alternative C9A	20	315 to 345
Alternative C14E	0	220
Segment D[a]		
Preferred Alternative D2A and D2A – 120th Station Design Option	30	376
D2A – NE 24th Design Option	30	382
Alternative D2E	0	348 to 356
Alternative D3	30	808 to 816
Alternative D5	0	239
Segment E[b]		
Preferred Alternative E2	0	20
E2 - Redmond Transit Center Design Option	16	94
Alternative E1	0	37
Alternative E4	0	45

[a] The range of off-street parking removal is due to connectors with Segments B and C.

[b] Segment C and E on-street parking is the total of unrestricted and restricted on-street parking. Restricted parking includes all parking spaces with special-use restrictions, such as drop-off/loading zones.

[c] C9T – East Main Station Design Option connecting from Preferred Alternative B2M would have no change in impacts on either Preferred Alternative C9T or B2M.

[e] Includes parking spaces removed at the station areas.

Notes: Indicated parking impacts are permanent displacements. Parking losses associated with construction are not included.

Segment B

Preferred 112th SE Modified Alternative (B2M)

Preferred Alternative B2M would remove 20 off-street parking spaces in properties along Bellevue Way SE and 112th Avenue SE and zero on-street spaces.

Other Segment B Alternatives

The B3 – 114th Extension Design Option is expected to require removing the most parking spaces of the eight alternatives proposed in Segment B. Most of these spaces are located in the Wilburton Park-and-Ride. Among the alternatives in Segment B, Alternative B3 would remove the fewest parking spaces, which are located in the Mercer Slough Park. None of the alternatives in Segment B are expected to remove on-street parking. No on- or off-street spaces would be removed for the proposed stations. There is a low potential for parking spillover to occur at the South Bellevue Station in year 2020, but there is some potential for parking spillover at this station in year 2030 when the expected 1,560 autos exceeds the proposed parking (approximately 1,400 stalls). Even though there could be a potential for spillover by year 2030, the potential spillover is expected to be low.

The South Bellevue Park-and-Ride lot is currently at capacity and there is minimal parking spillover in the nearby residential areas because most of the parking in the area is not easily identifiable and/or accessible from Bellevue Way. This is illustrated by the low on-street parking utilization in the Enatai neighborhood (Table 3-29). In addition, the City of Bellevue constructed a sidewalk and eliminated on-street parking on 112th Avenue SE, south of the South Bellevue park-and-ride, to remove the potential for hide-and-ride parking near the station.

At the SE 8th Station, there would be a low potential for hide-and-ride parking because of the recently established residential parking zone for the Surrey Downs neighborhood. Additionally, this parking is not easily accessible to the SE 8th Station location. At the 118th Station, there is a low potential for hide-and-ride impacts because the park-and-ride lot is expected to accommodate year 2020 and 2030 auto demand.

Segment C

Preferred 108th NE At-Grade Alternative (C11A)

Preferred Alternative C11A would remove approximately 10 on-street parking spaces—located along 108th Avenue NE—and 340 off-street parking spaces. These off-street parking spaces are parcels along 108th, 112th, and 116th Avenues NE and Main and NE 2nd Streets. With a connection to Alternative B3, B3 - 114th Extension Design Option or B7, 10 on-street parking spaces and 360 off-street parking spaces would be removed.

TABLE 3-29
Existing and Proposed Park-and-Ride Parking Stalls and Forecasted Auto Use

Station	Alternative	Total Existing Parking Stalls	Total Proposed Parking Stalls	2020 Park-and-Ride Auto Demand[a]	2030 Park-and-Ride Auto Demand[a]
Mercer Island[b]	*Preferred Alternative A1*	447	447	390	460
South Bellevue	*Preferred Alternative B2M* and Alternatives B1, B2A, B2E, and B3	519	1,400	1,310	1,560
118th	Alternative B7	-	1,030	580	760
130th[c]	*Preferred Alternative D2A* and Alternatives D2E and D3	-	300	270	380
Overlake Village	All D alternatives	203	203	260	480
Overlake Transit Center	All D alternatives	170	320	460	670
SE Redmond	All E alternatives	-	1,400	1,030	1,030
Redmond Transit Center	E2 – Redmond Transit Center Design Option	377	377	150	180

[a] The 3-hour PM peak-period park-and-ride auto demand from Sound Transit's transit ridership model; 3-hour PM peak-period is a close representation of daily park-and-ride demand.

[b] The park-and-ride auto demand is associated with Alternative B7. With any Segment B alternative that includes a South Bellevue Station, the park-and-ride forecast is less than the proposed number of parking stalls.

[c] With *Preferred Alternative D2A*, there is the potential to locate the park-and-ride lot at either the 130th Station or 120th Station. With either location, park-and-ride auto demand would be similar.

Preferred 110th NE Tunnel Alternative (C9T)

With *Preferred Alternative C9T*, no on-street parking spaces would be removed, but 385 off-street parking spaces would be removed, the highest of any Segment C alternative. These removed off-street parking spaces would be associated with parcels along 112th Avenue NE, Lake Bellevue Drive, and 116th Avenue NE and would include parking spaces for approximately 105 vehicles and 20 motorcycles at the Bellevue City Hall parking garage.

Other Segment C Alternatives

The parking impacts associated with each alternative in Segment C depend upon the connection to Segment B alternatives. For example, either Alternative C3T or C4A would remove the fewest off-street stalls of any Segment C alternative, depending on their connection to Segment B. Seven unrestricted on-street spaces and four on-street spaces that have been designated as short-term loading zones would be removed under Alternative C4A.

Alternative C9A would remove the most off-street parking spaces after *Preferred Alternatives C9T* and *C11A*. Additionally, approximately 20 on-street parking spaces would also be removed under Alternative C9A. Impacts on the Bellevue City Hall parking garage would be less than those described with *Preferred Alterative C9T*.

The design of the Bellevue Transit Center Station with the Alternative C3T would require the removal of off-street parking spaces in a private parking lot on the northeast corner of the NE 6th Street and 108th Avenue NE intersection. For Alternative C7E, this station is expected to require the removal of parking spaces on the southeast corner of the intersection of NE 6th Street and 112th Avenue NE.

No impacts on parking spaces are expected with the construction of the Old Bellevue, East Main, 108th, Hospital or Ashwood/Hospital stations for any alternative in Segment C.

In general, the stations in Segment C are designed to accommodate bus transfers, pedestrians, and bicyclists. These stations would not be attractive stations for auto access (and the potential for hide-and-ride parking) due to the surrounding congestion and restricted public parking opportunities. At the Old Bellevue, Ashwood/Hospital, and Bellevue Transit Center stations, there is some available nearby on-street parking; however, there is a low potential for hide-and-ride parking at these stations because most of the on-street parking provided in this area is either restricted or in private lots that are monitored. There is also a low potential for hide-and-ride parking at the East Main and Hospital stations because of the minimal amount of available on-street parking surrounding the stations. At the 108th Station, hide-and-ride parking would be unlikely because the City of Bellevue has established a residential parking zone in the Surrey Downs neighborhood.

Segment D

Preferred NE 16th At-Grade Alternative (D2A)

Preferred Alternative D2A would remove approximately 376 off-street parking spaces and 30 on-street parking spaces located on the north side of NE 16th Street between 132nd and 134th Avenues NE and on the east side of 136th Place NE between NE 16th and NE 20th Streets. The largest off-street parking impacts occur at the light industrial properties on the southwest end of Segment D near 120th Avenue NE between NE 14th and NE 15th Streets.

With the D2A – 120th Design Option, parking impacts would be similar to *Preferred Alternative D2A*. With the D2A - NE 24th Design Option, 382 parking spaces would be removed.

Other Segment D Alternatives

Alternative D3 would remove a relatively high number of off-street parking spaces, the largest being associated with a commercial space on the northwest corner of the intersection of NE 20th Street and 152nd Avenue NE. At an adjacent shopping center on the northeast corner of the intersection of NE 20th Street and 148th Avenue NE, parking spaces would be removed by Alternative D3. Alternative D3 would also require the removal of off-street parking spaces on multiple properties located along 152nd Avenue NE between NE 20th Street and NE 24th Street.

Alternatives D2E and D3 would affect the parking at light industrial properties at the southwest end of Segment D near 120th Avenue NE between NE 14th Street and NE 15th Street. Alternative D3 would have similar on-street parking impacts as *Preferred Alternative D2A*. Alternative D5 would remove the fewest off-street stalls of the Segment D alternatives.

Several areas where parking would be removed are near the 130th Station and the Overlake Village Station. Twenty off-street parking spaces near the 130th Station would be removed with *Preferred Alternative D2A,* D2E and Alternative D3. All of these affected parking spaces are located between 130th and 132nd Avenues NE, near NE 16th Street.

For *Preferred Alternative D2A,* the Overlake Village Station is located approximately 450 feet further north on the west side of 152nd Avenue NE from the existing Overlake Village Park-and-Ride. The *Preferred Alternative D2A* would remove parking spaces located in off-street parking lots adjacent to SR 520 and west of 152nd Avenue NE. For Alternative D2A – NE 24th Design Option and Alternative D2E, the design of the Overlake Village Station would require the removal of parking spaces located in private off-street parking lots on the northwest corner of the intersection of NE 24th Street and 152nd Avenue NE. Alternative D5 would affect the same private parking lots, but the number of affected parking spaces would vary depending on which of the two potential station locations is chosen. The design of the Overlake Village Station associated with Alternative D3 requires the removal of parking spaces located in private lots along 152nd Avenue NE, north of NE 24th Street.

At the 130th, Overlake Village, and Overlake Transit Center stations, there is a potential for parking spillover because the future parking forecast is higher than the station’s parking capacity. However, because there is a minimal amount of available on-street parking surrounding these stations, there is a low potential for hide-and-ride impacts. At the Overlake Transit Center, while the potential spillover could infringe on nearby private businesses, they are currently monitored. Therefore, hide-and-ride parking near this station is expected to be low.

Although there is currently available on-street parking that surrounds the 120th Station, planned land use and transportation changes surrounding the Bel-Red area could result in a decrease of available on-street parking and therefore a lower potential for hide-and-ride impacts. In Segment D, because there are numerous private parking lots surrounding the stations, measures such as security enforcement or time-limited parking by private owners would minimize the potential for hide-and-ride activities.

Segment E

Preferred Marymoor Alternative (E2)

Preferred Alternative E2 would have the least impact on parking of the four Segment E alternatives. A total of 20 off-street private parking spaces and zero on-street parking spaces would be removed under *Preferred Alternative E2.*

The E2 – Redmond Transit Center Design Option would have the greatest impact on parking of the four Segment E alternatives due to impacts along 161st Avenue NE. A total of 94 off-street private parking spaces and 16 on-street parking spaces would be removed. All of the on-street parking impacts would be located along 161st Avenue NE between NE 83rd and NE 85th Streets.

If the *Preferred Alternative E2* alignment adjacent to NE 76th Street requires the roadway to be reconstructed, its on-street parking may be removed.

Other Segment E Alternatives

Alternatives E1 and E4 would remove slightly more off-street parking than *Preferred Alternative E2* with 37 and 45 spaces, respectively.

The only station that would remove parking spaces in Segment E is the Redmond Transit Center Station with the E2 – Redmond Transit Center Design Option. This station would remove 30 off-street parking spaces located on the west side of 161st Avenue NE between NE 80th and NE 83rd Streets.

At the two stations with park-and-ride lots, Redmond Transit Center and SE Redmond, the expected auto forecasts would be less than the available parking capacity; therefore, there is a low potential for parking spillover at these stations. In addition, with the low amount of on-street parking available near the SE Redmond Station, there would not likely be hide-and-ride impacts at this station even if the parking demand exceeded the park-and-ride capacity.

At the Redmond Town Center and Downtown Redmond Stations, with no proposed park-and-ride lot and with a substantial amount of available on-street parking surrounding the station, high potential for hide-and-ride impacts could occur. However, the City of Redmond has recently implemented a restricted (time-limited) parking policy for much of their downtown area. This would limit hide-and-ride activity. Hide-and-ride parking could also occur in the neighboring retail center, but with the current security enforcement and planned time-limited parking, the potential for hide-and-ride activities in this development would be minimized. Owners of other private parking lots near the stations could implement measures such as security enforcement or time-limited parking that would minimize the potential for hide-and-ride activities in their parking lots.

3.6.4 Construction Impacts

Construction of the project alternatives would result in temporary impacts on arterials, local streets, and parking within the construction areas. While the overall construction duration would be about 7 years, most impacts would occur during the civil construction period (i.e. light rail and/or roadway construction) that would range from approximately 2 to 5 years in any given portion of the corridor.

Construction activities expected to have roadway impacts include utility relocation, roadway construction, light rail construction, truck hauling, demolition, and construction staging. The impacts from truck hauling were evaluated based on the number of truck trips and potential haul routes as discussed in the following subsection. For discussion of construction impacts on I-90, I-405, and SR 520, refer to Section 3.5; for construction impacts on transit, refer to Section 3.4. The *Transportation Technical Report* provides further discussion of the roadway impacts, including haul routes and truck trips, associated with the construction of each alternative.

3.6.4.1 Truck Volumes and Haul Routes

The exact number of construction truck trips that would be needed for the construction of each alternative is dependent on many variables that cannot be fully determined or finalized at this time, but an estimate was prepared to understand potential East Link Project construction impacts on the local and regional transportation system.

A range of truck trips is provided in Table 3-30 based on estimated quantities for the main trip generation activities, including imported fill material, concrete, asphalt concrete pavement, and excavated material that would be generated for the construction of each alternative. Truck trips associated with activities such as miscellaneous deliveries have not yet been quantified and are excluded from this estimate.

Preliminary truck haul routes were identified using the classified truck routes from WSDOT, King County, and the cities of Seattle, Bellevue, and Redmond, and are shown in Appendix G1. In general, multiple truck haul routes are proposed for each alternative based on access to regional transportation facilities and the alternative's route. Final truck haul routes would be determined in conjunction with the affected jurisdictions through the project's permitting processes.

Segment A

In Segment A, a relatively low amount of truck activity (less than 20 trucks per day) is expected because the alternative requires minimal excavation and import of loose materials. Trucks would access and use I-90 as a haul route. Trucks might also access a potential construction staging site within the I-90 right-of-way along Dearborn Street. In Segment A, the most intensive period of truck trips would last approximately 2 years.

Segment B

Of the alternatives in Segment B, *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* would likely require the most truck trips due to the amount of excavation and asphalt concrete pavement required. With this alternative, between 80 and 90 truck trips per day are estimated to be needed to access Bellevue Way SE, SE 8th Street, 112th Avenue SE, and 118th Avenue SE from I-90 and I-405. For all the Segment B alternatives, the trucks would access construction areas from these same streets. In Segment B, the most intensive period of truck trips would last approximately 2 to 3 years.

TABLE 3-30
Average Truck Trips for Construction of Alternatives

Alternative	Average Truck Trips To and From Location[a]	
	Per Day	Per Hour[b]
Segment A		
Preferred Alternative B, A, C	12 to 14	1 to 2
Segment B		
Preferred Alternative B2M to *Preferred Alternative C9T*	60 to 70	6 to 7
Preferred Alternative B2M to *Preferred Alternative C11A*	80 to 90	8 to 9
Alternative B1	54 to 66	5 to 7
Alternative B2A	35 to 42	3 to 4
Alternative B2E	18 to 23	2
Alternative B3	26 to 32	3
Alternative B7	24 to 30	2 to 3
Segment C		
Preferred Alternative C9T[c]	75 to 85	7 to 9
Preferred Alternative C11A	35 to 40	3 to 4
Alternative C1T	135 to 165	13 to 17
Alternative C2T	100 to 120	10 to 12
Alternative C3T	140 to 170	14 to 17
Alternative C4A	105 to 130	10 to 13
Alternative C7E	20 to 30	2 to 3
Alternative C8E	100 to 125	10 to 13
Alternative C9A	25 to 30	2 to 3
Alternative C14E	40 to 45	4 to 5
Segment D		
Preferred Alternative D2A	85 to 95	8 to 10
D2A – NE 24th Design Option	95 to 105	9 to 11
Alternative D2E	25 to 30	2 to 3
Alternative D3	50 to 60	5 to 6
Alternative D5	20 to 30	2 to 3
Segment E		
Preferred Alternative E2	55 to 65	5 to 7
E2 – Redmond Transit Center Design Option	55 to 70	5 to 7
Alternative E1	50 to 65	5 to 7
Alternative E4	50 to 60	5 to 6

[a] Truck trips presented are for connections to alternatives in adjacent segments that would produce the highest truck volumes.

[b] Assuming a minimum of 10 construction hours per day.

[c] C9T – East Main Station Design Option connecting from *Preferred Alternative B2M* only would have no change in impacts on either *Preferred Alternative C9T* or *B2M*.

Note: For haul origin/destination and preliminary truck haul routes for each alternative, refer to the Appendix H1, Transportation Technical Report, and the conceptual design drawings in Appendix G1.

Segment C

In Segment C, Alternative C3T would likely result in the greatest number of truck trips per day of the alternatives in Segment C. Between 140 and 170 truck trips per day would be required to access 108th Avenue NE and 112th Avenue NE between SE 8th and NE 12th Streets. In Segment C, the most intensive period of truck trips would last approximately 3 years for surface and elevated alternatives and approximately 4 years for tunneled alternatives. Generally, truck trips would access Segment C construction areas from I-405 via SE 8th, NE 4th, and NE 8th Streets.

Segment D

The D2A – NE 24th Design Option would require the most truck trips of all Segment D alternatives due to the amount of retained-cut, fill, and elevated structure. Between 95 and 105 truck trips per day could be expected with this alternative. In Segment D, the most intensive period of truck trips would last approximately 3 to 4 years. Generally, truck trips would access Segment D construction areas from SR 520 via 124th and 148th Avenues NE and NE 40th Street.

Segment E

In Segment E, each alternative would require about the same number of truck trips: between 50 and 70 trips per day. In Segment E, the most intensive period of truck trips would last approximately 2 to 3 years. These trips would likely be routed on a frontage road along SR 520 and along SR 202, West Lake Sammamish Parkway NE, and other streets.

Maintenance Facilities

For the proposed maintenance facilities in Segment D, the 116th Maintenance Facility (MF1) is expected to have the greatest number of truck trips, up to 140 per day. MF1 is located between 116th Avenue NE and the former BNSF Railway and has auto access to 120th Avenue NE. Truck trips are assumed to use the SR 520 interchange with 124th Avenue NE to deliver and haul materials. In Segment E, the SE Redmond Maintenance Facility (MF5) would require about 25 trips per day. The suggested truck route for this facility would use the SR 520 interchange with SR 202. The most intensive period of truck trips would last approximately 2 years.

3.6.4.2 Roadway and Parking Impacts

Construction impacts are estimated based on the level of design completed to date and the known construction activities. Traffic maintenance and construction plans would continue to be refined through the final design and permitting stages of this project and subject to approval by WSDOT and the cities of Bellevue, Seattle, Mercer Island, and

Redmond. The construction impacts, including construction truck traffic level, type and duration of road closure, availability of detour routes, and potential for neighborhood traffic intrusion, are detailed by segment in Table 3-31. Detour routes are available near most alternatives, but for detour routes that require longer out-of-direction travel, potential detour routes are identified. For roadways classified as collector or local arterials, these roads could be signed to only provide local access.

This section also discusses potential impacts for each of the maintenance facilities. For the preferred alternatives in Segments B and C, a PM peak-hour traffic analysis on the local streets and arterials is provided assuming the preliminary lane closures and possible detour routes described during the civil construction period. This was not performed for the preferred alternatives in Segments D and E as any roadway impacts would be on relatively low-volume local and collector streets therefore impacts to traffic would be less. This analysis is compared with the 2020 no-build condition, which indicates how the roadway conditions would change during the construction period. For nonpreferred alternatives, relative comparisons with the impacts described for the preferred alternatives are provided, where applicable.

For the discussion of the construction impacts on transit service and facilities, and to regional highways (I-90, I-405, SR 520), refer to sections 3.4.4 and 3.5.3.4, respectively.

Impacts Common to All Segments

In all segments, construction would affect roads, close lanes, require detours, and alter traffic patterns. Cross streets that intersect the alternatives would likely be partially closed for short durations to construct the track or other associated features through the intersection. Likewise, temporary closures of private driveways and any roads that need to be paved would also occur. If driveway closures are required, then property access to residences and businesses would be maintained to the extent possible. If alternative access is not available, then the specific construction activity would be reviewed to determine if it could occur during nonbusiness hours, or if parking could be provided at an alternative location.

A relatively high number of construction workers (producing traffic and requiring parking) would be needed to construct the project. The largest number of employees at any given site is anticipated during two periods: excavation for tunnel or retained-cut activities, and construction of the guideway and stations, especially if grade-separated. Contractors and construction workers parking near designated construction staging areas could affect area parking supply during heavy construction periods by using unrestricted on-street parking in residential or other areas near the construction site. The contractor is generally responsible for providing parking for construction workers where necessary. It is expected that some worker parking could be accommodated at the staging areas and along the route. Sound Transit or its contractors may lease parking for construction workers near construction sites. Sound Transit may acquire additional properties for temporary use for contractor parking.

Segment A, *Preferred Interstate 90 Alternative (A1)*

Within Segment A, short-term roadway shoulder and/or lane closures may occur on Rainier Avenue South, 23rd Avenue South, 77th Avenue SE and 80th Avenue SE for station area construction.

Segment B

Preferred 112th SE Modified Alternative (B2M)

Preferred Alternative B2M connecting to either *Preferred Alternative C11A* or *C9T* would result in construction impacts along Bellevue Way, south of 112th Avenue SE and along 112th Avenue SE north of Bellevue Way SE.

Along Bellevue Way SE, between the South Bellevue Park-and-Ride and 112th Avenue SE, one lane would likely be closed for most of the civil construction period, and additional lane closures could be required at certain times depending on the construction activity. To construct the improvements on Bellevue Way SE south of the South Bellevue Park-and-Ride, *Preferred Alternative B2M* would close lanes on Bellevue Way SE for short periods to install the traffic signals and perform the necessary roadwork.

Civil construction activities would likely close one northbound lane along Bellevue Way SE for the *Preferred Alternative B2M* with additional lane closures possible at times. Motorist information and advance signing would be provided to encourage usage of parallel routes, such as I-405. Even with signed detour routes, congestion would likely increase for northbound traffic on Bellevue Way SE between I-90 and 112th Avenue SE, and therefore, up to two intersections would operate at LOS F compared with one intersection in the no-build condition during the civil construction period. Additionally, increased congestion would be expected along the signed alternate routes. The potential for traffic to cut through the Enatai neighborhood and travel along 108th Avenue SE to bypass the construction zone along Bellevue Way SE during the afternoon peak would be low because cut-through routes in this area are limited and circuitous.

TABLE 3-31
Roadway Construction Impacts by Segment

Segment/Location	Alternative	Roadway Classification	Construction Truck Traffic[a]	Road Closure[b]	Detour of Traffic		On-Street Parking Loss?[c]	Bus Route Impact?
					Detour Route Available?[e]	Neighborhood Traffic Intrusion

TABLE 3-31 CONTINUED
Roadway Construction Impacts by Segment

Segment/Location	Alternative	Roadway Classification	Construction Truck Traffic[a]	Road Closure[b]	Detour of Traffic		On-Street Parking Loss?[c]	Bus Route Impact?
					Detour Route Available?[e]	**Neighborhood Traffic Intrusion**		
SR 520 on- and off-ramps at SR 202	*Preferred Alternative E2* and Alternative E2 – Redmond Transit Center Design Option and E4	State highway	Moderate	Partial, long-term	Yes, via West Lake Sammamish Parkway or SR 520 terminus	Low	No	No

[a] Low truck traffic is associated with alternatives that would have minimal fill, excavation, and concrete work; high truck traffic is associated with major fill, excavation, and concrete work. Moderate is between these two boundaries.

[b] Partial road closure assumes some lanes are open to traffic. Short- and long-term durations were determined to be less than or more than 1 year. Full short-term closures would be required for specific activities like station construction, retained cut and fill construction, column drilling, or girder placement, and can be as short as 1 night/day closure or as long as less than 1 year.

[c] On-street parking loss is characterized for street parking only and does not consider that some off-street parking might be lost due to the location of construction and staging areas.

[d] C9T – East Main Station Design Option connecting from *Preferred Alternative B2M* only would have no change in impacts on either *Preferred Alternative C9T* or *B2M*.

[e] Roadways classified as collector or local arterial could be signed to only provide local access during East Link civil construction. Additionally, if detour routes within the immediate vicinity are not available possible routes are suggested.

For *Preferred Alternative B2M* connecting to *Preferred Alternative C11A*, lane closures along 112th Avenue SE could include one northbound and one southbound lane from Bellevue Way SE to SE 6th.

For *Preferred Alternative B2M* connecting to *Preferred Alternative C9T*, one lane of 112th Avenue SE from Bellevue Way SE to SE 6th could be closed for some of the civil construction period. Similar to the construction impacts on Bellevue Way SE, depending on the construction activity, more or fewer lanes could be closed along 112th Avenue SE for short periods.

During construction along 112th Avenue SE for *Preferred Alternative B2M* connecting to *Preferred Alternative C11A*, traffic diversions to other parallel arterials, such as Bellevue Way SE and SE 8th Street, and regional facilities, such as I-405, would be likely. Although congestion would likely increase in the northbound and southbound directions on 112th Avenue SE, the number of intersections along 112th Avenue SE not meeting the City of Bellevue LOS threshold would be similar to the no-build condition. The probability of traffic using 108th Avenue SE between Bellevue Way SE and Main Street to bypass the construction zones along 112th Avenue SE would be discouraged by the existing traffic-calming devices (slow speeds and speed bumps) and motorist information and advance signing directing vehicles to other arterials and regional facilities.

For Preferred Alternative *B2M* connecting to *Preferred Alternative C9T,* some increase in congestion for the northbound traffic during the afternoon peak is expected with a northbound lane closed, but it would have lower impacts compared to *Preferred Alternative B2M* connecting to *Preferred Alternative C11A*.

Other Segment B Alternatives

With Alternative B1, construction impacts would affect Bellevue Way throughout the segment and would likely close multiple lanes (one northbound and one southbound lane) for some of the civil construction duration; also, additional lane closures could be required at certain times depending on the construction activity. Under Alternatives B2A, B2E, B3, and B3 - 114th Extension Design Option, construction impacts would occur along Bellevue Way south of 112th Avenue SE, and along 112th Avenue SE north of Bellevue Way. Alternatives B2A, B3, and B3 - 114th Extension Design Option would have roadway impacts similar to Alternative B1, and Alternative B2E would have roadway impacts similar to *Preferred Alternative B2M* along Bellevue Way south of 112th Avenue SE. Along 112th Avenue SE, these four alternatives (B2A, B3, B3 – 114th Extension Design Option, and B2E) would likely have impacts similar to those under *Preferred Alternative B2M*. Alternative B7 would result in construction impacts on 118th Avenue SE with short-term lane closures at certain times depending on the construction activity.

Detour routes for the Segment B alternatives along Bellevue Way and/or 112th Avenue SE (B1, B2A, B2E, B3, and B3 – 114th Extension Design Option) would be similar to *Preferred Alternative B2M*. Detour routes for Alternative B7 construction activities include I-405, Bellevue Way, and 112th Avenue SE, but would likely not be required because the traffic volumes on 118th Avenue SE are relatively low compared to volumes on Bellevue Way and 112th Avenue SE.

Traffic congestion for the alternatives along Bellevue Way SE or 112th Avenue SE is expected to be similar to or worse than the *Preferred Alternative B2M* depending on the number of lane closures. Traffic congestion with any lane closures proposed for Alternative B7 would likely be limited to along 118th Avenue SE.

Segment C

Preferred 108th NE At-Grade Alternative (C11A)

Preferred Alternative C11A would affect 112th Avenue SE near SE 6th Street, 108th Avenue NE between Main Street and NE 6th Street, and NE 6th Street between 108th and 112th Avenues NE. One or more lanes along 112th Avenue SE south of SE 6th Street would be closed for a short time for construction of the rail crossing from the median to the west side. For some of the *Preferred Alternative C11A* civil construction period, one eastbound lane on Main Street between 108th and 112th Avenues NE would likely be closed, but more or fewer lanes could be closed for short terms, depending on construction activities. Construction activities would close lanes along 108th Avenue NE. Property access to the residences and businesses along 108th Avenue NE between Main and NE 6th Streets would be maintained to the extent possible, either through access on 108th Avenue NE or alternative routes. Changes in property access would be coordinated with the appropriate residences and businesses. With any of the lane closures in downtown Bellevue, motorist information and advance signing would be provided that would encourage travel on parallel streets, and signal operations could be modified to optimize vehicle flow during construction.

Even with vehicles diverted to parallel streets, increased congestion would likely occur on 108th Avenue NE, and one intersection would operate at LOS F with the lane closures. In addition to 108th Avenue NE, 106th and 110th Avenues NE would likely also experience some increase in congestion as vehicles are detoured to avoid 108th Avenue NE.

Up to two additional intersections on these parallel streets between Main Street and NE 8th Street would operate at LOS F compared with the no-build condition.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, *Preferred Alternative C11A* would result in short-term temporary lane closures on 112th Avenue SE south of Main Street during the construction of the elevated track across 112th Avenue SE.

Preferred 110th NE Tunnel Alternative (C9T)

Preferred Alternative C9T would affect 112th Avenue SE near SE 6th Street, 110th Avenue NE between Main and NE 6th Streets, and NE 6th Street between 110th and I-405. One or more lanes along 112th Avenue SE south of SE 6th Street would be closed for the short-term construction of the at-grade crossing through the intersection of 112th Avenue SE and SE 6th Street. *Preferred Alternative C9T* would likely close one eastbound lane on Main Street between 110th and 112th Avenues NE, but more or fewer lanes also could be closed, depending on the construction approach. Construction activities would close some and possibly all lanes at times along 110th Avenue NE between Main and NE 6th Streets. Property access to the residences and businesses along 110th Avenue NE between Main and NE 6th Streets would be maintained to the extent possible either through access on 110th Avenue NE or alternative routes. Changes in property access would be coordinated with the appropriate residences and businesses. With any of the lane closures in downtown Bellevue, motorist information and advance signing would be provided that would encourage travel on parallel streets, and signal operations could be modified to optimize vehicle flow during construction.

Even with vehicles diverted to parallel streets, congestion would likely increase on 110th Avenue NE. In addition to 110th Avenue NE, 108th and 112th Avenues NE would likely also experience some increase in congestion as vehicles are detoured to avoid 110th Avenue NE. Up to three additional intersections, compared with the no-build condition, along these parallel streets between Main Street and NE 8th Street would operate at LOS F.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, *Preferred Alternative C9T* would have impacts similar to *Preferred Alternative C11A* crossing 112th Avenue SE.

Other Segment C Alternatives

Alternative C1T would affect Bellevue Way and NE 6th Street, and Alternative C2T would have impacts along 112th Avenue SE, 106th Avenue NE, and NE 6th Street along the alignment. Construction activities under Alternatives C1T and C2T would close lanes on the affected roadways. Property access to the residences and businesses along affected roadways would be maintained to the extent possible through those roadways or alternative routes. Increased congestion would likely occur along Bellevue Way under Alternative C1T and 106th Avenue NE under Alternative C2T. Adjacent roads would also likely experience increased congestion due to the lane closures. Alternative C3T would have impacts along the alignment on 112th Avenue SE, 108th Avenue NE, and NE 12th Street, but because of its construction methods, there would be fewer impacts along 108th Avenue NE relative to the Alternative C1T and Alternative C2T roadway impacts. For Alternative C3T, one or more lanes along 112th Avenue SE might be closed for a short time to construct the light rail crossing of 112th Avenue SE. One westbound lane on NE 12th Street between 108th and 112th Avenues NE would likely be closed, more or fewer lanes could be closed for short periods, depending on construction activities.

Alternative C4A would have impacts along 112th Avenue SE, Main Street, 108th Avenue NE, 110th Avenue NE, and NE 12th Street. Along 112th Avenue SE and NE 12th Street, impacts would be similar to those of Alternative C3T. Along Main Street, impacts would be similar to those under *Preferred Alternative C11A*. Along 108th and 110th Avenues NE, multiple lanes would be closed in order to convert the two-way traffic to a one-way couplet and to construct the light rail. Increased congestion would likely occur along both of these streets during the road modification and light rail civil construction periods.

With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, Alternative C4A impacts would be similar to those under *Preferred Alternative C11A* crossing 112th Avenue SE.

Alternative C7E would have impacts along 112th Avenue NE. Likely one northbound lane on 112th Avenue NE from the southern Segment C boundary to NE 12th Street would be closed during construction activities. With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, no additional roadway impacts would be experienced.

Alternative C8E would have impacts along the alignment on 114th Avenue, NE 2nd Street, 110th Avenue NE between NE 2nd Street and NE 12th Street, and NE 12th Street. One lane on 114th Avenue SE and one or more lanes on 110th Avenue NE would likely be closed during construction activities.

Alternative C9A would have impacts along 112th Avenue SE, 110th Avenue NE between Main and NE 6th Street, and NE 6th Street between 110th Avenue NE and 112th Avenue NE. With a connection to Alternative B3, B3 - 114th Extension Design Option, or B7, Alternative C9A would have construction impacts along 112th Avenue SE similar to *Preferred Alternative C11A*.

Alternative C14E would have impacts along 114th Avenue NE. Property and emergency access along 114th Avenue NE between Main and NE 6th Streets would be maintained either through access on 114th Avenue NE or alternate routes. This is not expected to create traffic impacts beyond this roadway.

Detour routes would be determined through final design and construction permitting. Because of the gridded street network in Downtown Bellevue, detour routes would likely be provided via adjacent parallel streets. Neighborhood traffic intrusion would range from low to moderate, depending on whether the construction activity occurs near residential areas to the north and south of downtown, but for most of the construction period neighborhood traffic intrusion would be minimal. Where partial and full roadway closures occur, increased congestion can be expected at adjacent intersections as vehicles avoid construction areas.

Within Segment C where tunneled alternatives cross roadways, short-term full street closures would likely occur. These closures are necessary for material excavation at these locations, such as the intersections of Main, NE 2nd, and NE 4th Streets with 110th Avenue NE under *Preferred Alternative C9T.*

Segment D

Preferred NE 16th At-Grade Alternative (D2A)

Preferred Alternative D2A would have roadway impacts along NE 16th Street (between 132nd Avenue NE and 136th Place NE), 136th Place NE, and Microsoft Road. At-grade crossings would occur at 130th Avenue NE, 132nd Avenue NE, 136th Place NE, and NE 20th Street. Property access along NE 16th Street and 136th Place NE would be maintained to the extent possible through access either on these streets or on an alternate route, depending on the construction activity. However, short periods of full closures might occur along NE 16th Street and 136th Place NE. Increases in congestion are expected to remain isolated to these low-volume roadways and not extend into surrounding arterials.

The D2A – 120th Design Option would have impacts similar to the *Preferred Alternative D2A* with an additional at-grade crossing at 120th Avenue NE. The D2A – NE 24th Design Option would have roadway impacts similar to those under *Preferred Alternative D2A*, except that one lane along NE 24th Street and 152nd Avenue NE could be closed for most of the civil construction period and additional lane closures could be required at certain times, depending on the construction activity.

Detours would be available through many of the parallel arterial routes available in Segment D. The potential for detoured traffic and construction vehicles in neighborhood areas would be low because there is not a substantial amount of residential development in the area and the construction would occur on or near designated truck routes. There would be some on-street parking loss associated with construction impacts within Segment D.

Other Segment D Alternatives

Alternative D2E would have impacts along NE 16th Street, 136th Place NE, NE 24th Street, 152nd Avenue NE, and Microsoft Road. Alternative D3 would have impacts along NE 16th Street, 136th Place NE, NE 20th Street, 152nd Avenue NE, and Microsoft Road with at-grade crossings of 120th Avenue NE, 124th Avenue NE, 130th Avenue NE, 132nd Avenue NE, 136th Place NE, NE 20th Street, 140th Avenue NE, Ross Plaza entrance (14300 block), and NE 24th Street.

With Alternatives D2E and D3, impacts along the existing NE 16th Street and 136th Place NE would be similar to those under *Preferred Alternative D2A.* Along NE 24th Street and 152nd Avenue NE, Alternative D2E impacts would be similar to those under D2A – 24th Design Option. Alternative D3 could have multiple lanes closed along NE 20th Street and 152nd Avenue NE for most of the civil construction period, and additional lane closures could be required at certain times, depending on the construction activity. During periods of multiple lane closures, increased traffic congestion and poor intersection operations would likely occur along NE 20th Street.

Alternative D5 would have impacts along Microsoft Road similar to the *Preferred Alternative D2A*.

Traffic detours would be available under Alternative D3 during the construction along NE 20th Street and 152nd Avenue NE. Motorist information and signs directing vehicles to other arterials (NE 24th Street, Bel-Red Road, and 156th Avenue NE) would be provided. All other alternatives would have detours similar to those under *Preferred Alternative* D2A, with the exception of Alternative D5, which would have no detours.

Segment E

Preferred Marymoor Alternative (E2)

Preferred Alternative E2 would have impacts at the SR 520 on- and off-ramps at SR 202 and with the at-grade crossings at Leary Way, 164th Avenue NE, 166th Avenue NE, and 170th Avenue NE. All Segment E alternatives would have grade-separated crossings of NE 40th, NE 51st, and NE 60th Streets, with multiple lanes closed for most of the civil construction period, and additional lane closures could be required at certain times depending on the construction activity. Increased traffic congestion would likely occur during multiple lane closures on the NE 40th Street overpass during civil construction activities. Detours to adjacent SR 520 crossings and interchanges would be provided. NE 70th Street would be a full closure also for all Segment E alternatives.

The E2 – Redmond Transit Center Design Option would have the same impacts as *Preferred Alternative E2,* in addition to impacts along 161st Avenue NE between Redmond Way and NE 85th Street. 161st Avenue NE would likely be closed for most of the civil construction period. Property access along 161st Avenue NE between Redmond Way and NE 85th Street would be maintained to the extent possible either through access on 161st Avenue NE or alternative routes.

Detours through the commercial areas would occur along parallel routes (160th or 164th Avenues NE if 161st Avenue NE is closed). Throughout Segment E for all Segment E alternatives, the potential for traffic to detour through residential neighborhoods is low as most of the construction activities occur along SR 520 and in Downtown Redmond. There would be some on-street parking loss associated with construction impacts within Segment E.

If the *Preferred Alternative E2* alignment adjacent to NE 76th Street requires the roadway to be reconstructed, it would be constructed prior to the East Link construction along this section of roadway.

Other Segment E Alternatives

Alternative E1 would have impacts at the Leary Way, 164th Avenue NE, 166th Avenue NE, and 170th Avenue NE crossings, and on NE 70th Street. The Leary Way Alternative (E4) would have impacts along Leary Way, 164th Avenue NE, 166th Avenue NE, 170th Avenue NE, and NE 70th Street, and at the SR 520 on- and off-ramps at SR 202. Many of the construction impacts and potential detours under Alternatives E1 and E4 would be similar to *Preferred Alternative E2*.

Maintenance Facilities

Constructing the maintenance facilities would temporarily close streets that intersect the track leading to and from the maintenance facility. These closures would most likely occur during off-peak hours to avoid traffic disruptions and would generally last for less than a week. Also, private driveways and any roads that need to be paved could be temporarily closed. Otherwise, there would be no impacts from construction of the maintenance facilities.

3.6.5 Potential Mitigation

This section discusses mitigation for impacts on intersection LOS and parking during project operation, and mitigation for impacts during project construction. Final mitigation would be coordinated with each affected jurisdiction through subsequent phases of this project.

3.6.5.1 Intersection Level of Service

Arterial and local street mitigation is potentially required at intersections where the intersection LOS with the East Link Project, compared with the no-build condition, would degrade to levels that do not meet the LOS standards of the jurisdiction. The intersections that are potentially affected and their related improvements are discussed in the following subsections.

Segment A

In Segment A, no mitigation would be required in the City of Seattle. However, several intersections on Mercer Island might potentially require turn pockets or traffic signal improvements to adjust for the change in travel patterns to and from the island. Improvements at intersections within the City of Mercer Island's jurisdiction would include:

- West Mercer Way and 24th Avenue SE: Provide southbound left-turn pocket (*Preferred Alternative A1* and both eastbound HOV off-ramp design options at Mercer Island).
- 80th Avenue SE and SE 27th Street: Install a traffic signal (*Preferred Alternative A1* and both eastbound HOV off-ramp design options at Mercer Island).
- 77th Avenue SE and Sunset Highway: Install a traffic signal (design option that provides an eastbound HOV off-ramp at 77th Avenue SE).
- 77th Avenue SE and North Mercer Way: Install a traffic signal (*Preferred Alternative A1* and both eastbound HOV off-ramp design options at Mercer Island).

Improvements at intersections within WSDOT's jurisdiction include:

- 77th Avenue SE and I-90 eastbound HOV off-ramp: Install a traffic signal (design option that provides an eastbound HOV off-ramp at 77th Avenue SE).
- 77th Avenue SE and I-90 eastbound off-ramp: Install a traffic signal (*Preferred Alternative A1* and design option that provides no eastbound HOV off-ramp at Mercer Island).
- 76th Avenue SE/North Mercer Way and I-90 Westbound on-ramp: Modify the westbound channelization to provide left-turn pocket and through/right shared lane (*Preferred Alternative A1* and both eastbound HOV off-ramp design options at Mercer Island).

All of these improvements would improve the AM and PM peak-hour intersection delay to the same as or better than the no-build conditions. Sound Transit would be responsible for implementing improvements at the WSDOT-controlled intersections prior to East Link opening service. Sound Transit would contribute a proportionate share of costs to improve project-affected intersections controlled by Mercer Island. Sound Transit's contribution would be determined by the project's ratio of trips at the intersection or another equitable method. Through this contribution, the City of Mercer Island may determine other improvements than the intersection modifications listed that are more compatible with Downtown Mercer Island. Refer to Appendix H1, *Transportation Technical Report*, for the intersection results with these proposed intersection improvements.

Segment B

Depending on the Segment B alternative, the project would potentially require mitigation at the following intersections (with *Preferred Alternative B2M*, no intersection mitigation is required):

- 112th Avenue SE and Bellevue Way SE: Provide a northbound right-turn pocket (Alternatives B1, B2A, B3 and B3 – 114th Extension Design Option).
- 112th Avenue SE and SE 15th Street: Install a traffic signal (Alternatives B1, B2E, and B7).
- Coal Creek Parkway and I-405 southbound ramps: Provide an additional westbound left-turn pocket (Alternative B7).
- 118th Avenue SE and SE 8th Street/I-405 southbound on ramp: Provide a northbound right-turn pocket (Alternative B7).

While not considered mitigation, as part of the East Link Project, two roadway options that modify Bellevue Way SE near the South Bellevue Station are proposed for alternatives that include this station. These modifications are proposed to improve the station and neighborhood access and are described in Section 3.6.3.2.

Segment C

Depending on which Segment C alternative is selected, the project would potentially require mitigation at the following intersections:

- Bellevue Way and Main Street: Provide a northbound right-turn pocket (Alternative C1T).
- 112th Avenue NE and NE 12th Street: Provide a westbound right-turn pocket (Alternatives C3T, C7E, and C8E).
- 112th Avenue NE and Main Street: Provide an eastbound right-turn pocket (*Preferred Alternative C11A*).
- 110th Avenue NE and NE 8th Street: Provide an eastbound right-turn pocket (Alternatives C4A and C9A). Provide a northbound right-turn pocket (Alternative C8E).
- 108th Avenue NE and NE 12th Street: Provide a northbound right-turn pocket (Alternative C4A).

Additionally, at the intersections listed below, mitigation to better use the roadway capacity could be implemented, such as providing active traffic management strategies. For example, active signing could be installed to more effectively route vehicles to less congested streets, turn movements could be restricted during congested periods, or adaptive signal controllers could be installed to better respond to changing traffic conditions:

- Main Street and 108th Avenue NE (*Preferred Alternative C11A)*
- NE 4th Street and 108th Avenue NE (*Preferred Alternatives C11A* and *C9T*, and Alternatives C1T, C2T, C3T, C8E, and C9A)
- NE 6th Street and 110th Avenue NE (Alternative C9A)
- NE 8th Street and 112th Avenue NE (Alternatives C4A and C8E)

Segment D

Depending on which Segment D alternative is selected, the project would potentially require mitigation at the following intersections:

- 120th Avenue NE and NE 16th Street: Provide a southbound right-turn pocket (D2A – 120th Design Option, year 2020 only; once background improvements along 120th Avenue NE are completed this intersection will operate acceptably with the project).
- 152nd Avenue NE and NE 24th Street: Provide a southbound right-turn pocket (All Segment D alternatives except Alternative D3). This or a similar intersection improvement would be coordinated with the City of Redmond.
- 148th Avenue NE and NE 20th Street: Accelerate planned eastbound and westbound left-turn improvements by year 2030 (Alternative D3).

Alternative D2E would require mitigation at the intersections of 151st and 152nd Avenues NE on NE 24th Street. The increase in delay would result from the two intersections being closely spaced and the intersection phasing and timing needed so that the light rail train can safely travel across NE 24th Street. As the light rail train approaches this street crossing, the traffic signals would only serve the westbound approach at 151st Avenue NE and the eastbound approach at 152nd Avenue NE to release any stopped or queued vehicles in this roadway section. Once the section is clear of vehicles, the light rail train could then proceed. While this might not substantially delay the light rail train, it might create unacceptable vehicle operations on NE 24th Street. If the track were to be realigned through the NE 24th Street and NE 152nd Avenue NE intersection, then it would remove the need to provide a vehicle clearance phase prior to the train arriving. With this realignment the alternative would be similar to Alternative D3, north of the intersection of 152nd Avenue NE and NE 24th Street.

Segment E

Depending on which Segment E alternative is selected, the project would potentially require mitigation at the following intersections:

- NE 76th Street and 170th Avenue NE: Install a traffic signal (all Segment E alternatives and Redmond Town Center interim terminus station).
- SR 202 and NE 70th Street: Provide a southbound right-turn pocket (all Segment E alternatives).
- Redmond Way and 161st Avenue NE: Provide a westbound right-turn pocket (E2 – Redmond Transit Center Design Option only); this improvement might be included as part of the City’s future roadway improvements, but has yet to be designed.
- SR 202 and East Lake Sammamish Parkway: Rechannelize to provide an additional southbound through lane (all Segment E alternatives).
- NE 70th Street and 176th Avenue NE: Install a traffic signal (*Preferred Alternative E2*, E2 – Redmond Transit Center Design Option).

3.6.5.2 Parking

Mitigation may be required where there are potential impacts on parking around stations. The potential for hide-and-ride activities near stations and the best ways to mitigate such activities is specific to each area surrounding a station. Stations that may generate hide-and-ride users are locations where the auto forecast is higher than the available parking at the station, or the station does not provide parking, and there is a substantial amount of on-street parking available surrounding the station. The station most likely to generate hide-and-ride impacts is the Rainier Station. At the Mercer Island and South Bellevue stations, the parking analysis determined a low potential for hide–and-ride impacts. However, given the locations of these stations, Sound Transit will evaluate hide-and-ride impacts within one year of East Link operations. If impacts are determined, Sound Transit would implement appropriate mitigation measures as discussed in this section.

Prior to implementing any parking mitigation measures, Sound Transit would inventory on-street parking around each of the three stations listed up to one year prior to the start of light rail revenue service. These inventories would document the current on-street parking supply within a quarter-mile radius of the stations. Based on the inventory results, Sound Transit and the local jurisdiction would work with the affected stakeholders to identify and implement appropriate mitigation measures, if necessary.

Parking control measures could consist of parking meters, restricted parking signage, passenger and truck load zones, and residential parking zone (RPZ) signage. Other parking mitigation strategies could include promotion of alternative transportation services (e.g., encourage the use of buses, vanpool or carpool services, walking, or bicycle riding).

For parking controls agreed to with the local jurisdiction and community, Sound Transit would be responsible for the cost of installing the signage or other parking controls and any expansion of the parking controls for one year after opening the light rail system. The local jurisdictions would be responsible for monitoring the parking controls and providing all enforcement and maintenance of the parking controls. The local residents would be responsible for any RPZ-related costs imposed by the local jurisdiction.

3.6.5.3 Construction Mitigation

All mitigation measures associated with East Link Project construction would comply with local regulations governing construction traffic control and construction truck routing. Sound Transit would finalize detailed construction mitigation plans in coordination with local jurisdictions and WSDOT during the final design and permitting phase of the project. Mitigation measures for traffic impacts due to light rail construction could include the following:

- Follow standard construction safety measures, such as installation of advance warning signs, highly visible construction barriers, and the use of flaggers.
- Use lighted or reflective signage to direct drivers to truck haul routes and enhance visibility during nighttime work hours.
- Use temporary reflective truck prohibition signs on streets with a high likelihood of cut-through truck traffic.
- In areas with high levels of traffic congestion, schedule traffic lane closures and high volumes of construction traffic during off-peak hours to minimize delays where practical.
- Communicate public information through tools such as print, radio, posted signs, websites and email to provide information regarding street closures, hours of construction, business access, and parking impacts.
- Coordinate access closures in person with affected businesses and residents. If access closures are required, property access to residences and businesses would be maintained to the extent possible. If access to the property is not able to be maintained, the specific construction activity would be reviewed to determine if it could occur during nonbusiness hours, or if the parking and users of this access (for example deliveries) could be provided at an alternative location.
- Where necessary, ensure that the contractor is responsible for providing parking areas for construction workers.

For potential transit (and associated park-and-ride) and regional highway (I-90, I-405, and SR 520) mitigation during East Link Project construction, refer to Sections 3.4 and 3.5, respectively.

3.7 Nonmotorized Facilities

3.7.1 Methodology

Within the study area, Sound Transit inventoried existing nonmotorized facilities consisting of sidewalks, designated bicycle routes, marked bicycle lanes, and regional multiuse trails. Sidewalks were inventoried and evaluated along arterial streets within an area 0.5 mile from proposed stations, and bicycle routes were inventoried within an area one mile from stations. Missing sidewalk areas were identified on either one or both sides of arterial streets in consideration of local agency comprehensive plan and transportation element policies.

Regional multiuse trails as well as local agency-recommended school walk routes were identified and analyzed for any potential impacts based on their proximity to stations. Surrounding land uses, sidewalk and bicycle facilities and their barriers were included in the nonmotorized analysis evaluating the existing and future nonmotorized activity surrounding each proposed station. Tables 7-6, 7-9, 7-11, 7-13, and 7-15 in Section 7 of the *Transportation Technical Report* (Appendix H1) provide further detail on the pedestrian and bicycle activity discussed in this section. Pedestrian LOS was also analyzed within 300 feet of station entrances using the methodology from the *Highway Capacity Manual* (TRB, 2000) and the *Transit Capacity and Quality of Service Manual* (Transit Cooperative Research Program, 2003). For a more in depth discussion on nonmotorized facilities refer to Section 7 in the *Transportation Technical Report* (Appendix H1).

3.7.2 Affected Environment

3.7.2.1 Pedestrian Activity, Sidewalks, and School Walk Routes

Sidewalks are available along most arterial streets within the study area, providing sufficient pedestrian connections. Generally, there are only a few areas that are missing sidewalks on one or both sides of the street. Exhibits 7-1 through 7-12 in Section 7 in the *Transportation Technical Report* (Appendix H1) provide further detail on the sidewalks and trails in the study area. Streets that lack sidewalks are typically in residential neighborhoods, on local access streets, or on streets with low pedestrian volumes. The following subsections describe the pedestrian activity, sidewalks, and crosswalks in each segment.

Pedestrian Level of Service

A measure of the walking conditions on a sidewalk, route, or path. LOS A represents ample spacing between pedestrians on a sidewalk or path, allowing for free-flow walk speeds. LOS F represents unavoidable crowding between pedestrians on a sidewalk or path, preventing free-flow walking speed and movement.

Segment A

The Rainier Station in Segment A is located between the Central Area and North Rainier Valley neighborhoods in Seattle. Pedestrians using bus facilities in this area mostly originate from or are destined to the surrounding neighborhoods, including the International District. A few small segments with missing sidewalks, less than .25 mile in length, were identified along Rainier Avenue South. Crosswalks are present at most arterial intersections in this area. Sidewalks are present along both sides of Rainier Avenue S, south of I-90. North of I-90, sidewalks are present along the western side of Rainier Avenue South. On the east side of Rainier Avenue South, under I-90, the sidewalk terminates and connects to a paved trail that continues into Judkins Park and Playfield. The crosswalk and sidewalk configuration in this area is discontinuous and, therefore, can create slightly longer walking distances for pedestrians. Additionally, there is a midblock crossing on 23rd Avenue South connecting South Day Street to the western portion of the I-90 Lid Park and Rainier Station. Generally, pedestrian and bicycle circulation in this area is from residents and some commercial users as well as recreational users where Judkins Park connects to the I-90 trail.

On Mercer Island, a more walkable area has been created in the northern part of the island as a result of recent mixed-use developments at the Mercer Island Town Center, completion of the new Mercer Island Park-and-Ride Lot, and improvements in pedestrian connectivity between the Town Center and North Mercer Island. Nearly all of the commercial activity in Mercer Island is centralized at the Mercer Island Town Center, making it a common destination for residents and pedestrians. The Mercer Island I-90 Lid Park provides multiple connection points across I-90 between North Mercer Island and the Town Center and provides the largest area of nonmotorized recreational use on Mercer Island.

Sidewalks located along 76th Avenue SE, 77th Avenue SE, and 80th Avenue SE provide pedestrian and bicycle connectivity across I-90. Crosswalks and wider sidewalks are present throughout most of the commercial area on Mercer Island in addition to some pedestrian-friendly roadway elements such as bulb-outs and street trees.

School walk routes are not present on arterial streets within Segment A.

Segment B

The South Bellevue Park-and-Ride Lot is the primary transit facility serving the South Bellevue neighborhoods. Pedestrian activity around this park-and-ride area is not as high as in other areas in the study area because of the surrounding residential neighborhoods and Mercer Slough Nature Park. Crosswalks are located at the signalized entrance to the park-and-ride lot. Sidewalk is absent along the western side of Bellevue Way SE, south of 112th Avenue SE, because of right-of-way constraints associated with the topography. Common walking origins or destinations in this area include the Enatai neighborhood, nearby office parks, and the Mercer Slough recreational area.

The existing sidewalks surrounding the proposed 118th and SE 8th stations are generally present along arterial streets, although sidewalks are absent on the east side of 114th Avenue NE (along I-405) and 118th Avenue SE because of right-of-way constraints. At the interchange of SE 8th Street and I-405, crosswalks are marked along the north side of SE 8th Street, although they are absent along the south side of SE 8th Street.

In Segment B, a missing sidewalk was also identified on SE 25th Street, which serves the school walk route for Enatai Elementary School. Most of the school walk routes for this school are located on collector and local residential streets.

Segment C

The highest pedestrian activity in Segment C and in the study area is focused around the Bellevue Transit Center in Downtown Bellevue. Currently, almost 700 pedestrians during the PM peak hour cross through the intersection of 108th Avenue NE and NE 6th Street (adjacent to the Bellevue Transit Center). Many pedestrians using this transit center originate from or are destined to nearby employers throughout downtown. An east-west pedestrian pathway provides connectivity between the Bellevue Transit Center and the Bellevue Square Mall/Lincoln Square and surrounding retail uses. Sidewalks and crosswalks are generally present throughout Segment C.

The City of Bellevue has installed or signalized several midblock crosswalks within the downtown area to improve the connectivity between major destinations and land uses.

East of I-405, pedestrian activity occurs near the Overlake Hospital. Crosswalks and sidewalks are present along 116th Avenue NE. Pedestrian connectivity between Downtown Bellevue and the Overlake Hospital area is limited to a few connections across I-405. Crosswalks and sidewalks are also present along NE 8th Street east of I-405, although there is a considerable distance between the crosswalk locations at the 116th and 120th Avenue NE intersections.

Sidewalks are present along arterials that serve the Bellevue High School walk route in Segment C. Similarly to the other segments, many of the school walk routes are located on collector and local streets.

Segment D

Pedestrian activity in Segment D is lower than in the other segments. Most pedestrian activity in Segment D occurs east of 140th Avenue NE near the area surrounding Overlake Village, where retail, medical, and commercial uses are more predominant, and between the Overlake Transit Center and surrounding commercial and office land uses. More sidewalks and traffic signals are present in these areas than in the western part of Segment D.

Pedestrian activity in the Bel-Red area between 116th and 140th Avenues NE is minimal because much of the current land use consists of light industrial, office park, and commercial uses. Either no sidewalk is provided or large portions of missing sidewalk occur on both sides of arterial streets in this area (120th, 124th, 130th, and 136th Avenues NE). Additionally, long walking distances between the two east-west arterials, Bel-Red Road and NE 20th Street, discourage pedestrian activity in this area. However, there are sidewalk facilities on both sides of NE Bel-Red Road and NE 20th Street. Crosswalks are located at all signalized intersections in Segment D.

School walk routes are not present on arterial streets within segment D.

Segment E

Pedestrian activity is high within the Downtown Redmond, Redmond Town Center, and Marymoor Park areas because sidewalks, bicycle lanes, and recreational facilities have contributed to a more walkable area. Sidewalks are generally present within Segment E, although there are some sidewalks gaps on Bear Creek Parkway and 166th Avenue NE between Redmond Town Center and Downtown Redmond. Although the Redmond Town Center and Marymoor Park are popular pedestrian destinations, they are separated by SR 520, which presents a barrier for pedestrians wishing to cross between the two areas. The Sammamish River Trail passes beneath SR 520 at the West Lake Sammamish Parkway interchange and provides a pedestrian connection between the park and Downtown Redmond. Crosswalks are present at all signalized intersections in Segment E with the exception of the SR 520 entrance/exit ramps along NE 76th St and NE Redmond Way.

A school walk route for the Redmond Elementary School is located within a 0.5-mile radius of the Redmond Town Center Station.

3.7.2.2 Bicycle Routes, Bicycle Lanes, and Multiuse Trails

Trails used only for recreation are not addressed in this section. For information about recreational facilities, see Section 4.17, Parkland and Open Space, of the Final EIS. The exhibits in Section 7 of the *Transportation Technical Report* (Appendix H1) indicate where existing bicycle facilities are present for arterials within the study area.

Throughout the East Link study area, while there are bicycle lanes present on some arterials, designated and signed bicycle routes are located on most arterial or collector streets. Some arterials in the study area also have a wide shoulder that allows bicycle activity. Designated bicycle routes, marked bicycle lanes, and regional multiuse trails include 12th Avenue South in Seattle; the I-90 trail (includes North Mercer Way) on Mercer Island; Bellevue Way, 108th Avenue SE, 112th Avenue SE, 118th Avenue SE, NE 20th and 24th Streets, and 140th Avenue NE in Bellevue; and 156th Avenue, West and East Lake Sammamish Parkway, and SR 202/Redmond Way in Redmond.

In Seattle, 12th Avenue South is a designated bicycle route, and there are marked bicycle lanes on South Dearborn Street and Martin Luther King Jr. Way South. East-west bicycle connectivity to these streets is achieved primarily through routes on collector and local streets. There are bicycle facilities and sidewalk facilities on both sides of most arterial streets on Mercer Island, including North Mercer Way, Island Crest Way, and 78th Avenue SE. Bicycle activity in Segment B occurs more frequently along the I-90 Trail through Bellevue, within the local street network in the Enatai and Beaux Arts neighborhoods, and within the Mercer Slough recreational area. There are designated routes on some arterial streets in Segment C along 112th and 116th Avenues NE that connect to the SR 520 multiuse trail. Within Segment D, designated bike routes are present on some local and arterial streets north of NE 24th Street in the Cherry Crest neighborhood. The SR 520 multiuse trail provides most of the continuous bicycle coverage through Segment D. In the City of Redmond, bicycle lanes are present along segments of NE 85th Street, NE 83rd Street, and 171st Avenue NE. Most other streets through Downtown Redmond are designated bicycle routes. The Sammamish River Trail, Bear Creek Parkway Trail, and Marymoor Park trail network are bicycle facilities.

Multiuse trails provide regional mobility for nonmotorized users. There are several regional multiuse trails within the study area, and some of the accesses to these trails are located within close walking or bicycle distance to the stations, providing transit commuters with a location to easily transfer to and from nonmotorized modes. Regional multiuse trails located in the project vicinity include the I-90 Multiuse Regional Trail (Mountains to Sound Greenway), Mercer Slough Nature Park and Multiuse trails, SR 520 Regional Trail, Bridle Crest Trail, Sammamish River Trail, East Lake Sammamish Trail, and Bear Creek Trail. These trails are connected to one another by local designated bicycle routes. In Segment D, access to the SR 520 Regional Trail is provided along various arterials in the area. In Segment E, the SR 520 Regional Trail is accessible through public park areas and a few access points along the trail from designated bicycle routes on arterial streets.

3.7.3 Environmental Impacts

In the no-build condition, pedestrian and bicycle facilities would improve with numerous planned improvements included in agency long-range plans. The East Link Project would support, and in most cases enhance, these improvements as the project proposes a number of nonmotorized amenities in and around stations to minimize impacts on pedestrian and bicycle circulation, both during construction and after light rail is operational.

Transit facility designs would be flexible, allowing each station to reflect and fit into the community it serves while providing standard features to facilitate smooth and accessible transfers for transit customers from one type of transportation to another. Standard design features would include the following:

- Security and safety design standards
- Easy-to-read and consistent signs
- Pedestrian-friendly design and full access for people with disabilities
- Bicycle access and storage
- Sidewalks immediately adjacent to stations as shown on the conceptual design drawings in Appendix G1

Each station would provide bicycle storage, including racks and often lockers. The proposed number of bicycle facilities at the light rail stations is listed in the tables in the Environmental Impacts discussion of Section 7.0 of the *Transportation Technical Report*

(Appendix H1). Stations would include additional capacity for further expansion of bicycle racks and lockers in the future. Because of the proximity of some stations to regional trails such as the I-90 Regional Trail, the East Lake Sammamish Trail, and the potential BNSF Railway trail, wayfinding signage for nearby regional trails and other local destinations could be incorporated into station site design elements.

Estimates of PM peak-period pedestrian and bicycle trips generated by each station, as shown in Table 3-32, were used to qualitatively assess the degree of nonmotorized user activity in station areas. As expected, the stations with the highest number of pedestrian and bicycle trips—East Main, Old Bellevue, Bellevue Transit Center, and Overlake Transit Center—are located near major employment and residential areas (Downtown Bellevue and Overlake).

TABLE 3-32
PM Peak-Period (3-Hour) Pedestrian and Bicycle Trips Generated at Stations

Station	2020 Pedestrian and Bicycle Trips[a,b]	2030 Pedestrian and Bicycle Trips[a,b]
Segment A		
Rainier Station (*Preferred Alternative A1*)	600	660
Mercer Island Station (*Preferred Alternative A1*)	360	490
Segment B		
South Bellevue (*Preferred Alternative B2M* and Alternatives B1, B2A, B2E, B3, and B3 – 114th Extension Design Option)	90	130
SE 8th (*Preferred Alternative B2M* to *Preferred Alternative C9T* and Alternatives B2A and B2E)	240	290
118th (Alternative B7)	280	420
Segment C		
108th (*Preferred Alternative C11A*)	970	1,210
East Main (*Preferred Alternative C9T* and Alternatives C3T, C4A, C2T, C7E, C8E, and C9A)	970	1,450
Old Bellevue (Alternative C1T)	890	1,200
Bellevue Transit Center (*Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C3T, C4A, C7E, C8E, C9A, and C14E)	3,150	3,770
Ashwood/Hospital (Alternatives C3T, C4A, C7E, and C8E)	580	580
Hospital (*Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C9A, and C14E)	380	910
Segment D		
120th (*Preferred Alternative D2A*, D2A – 120th Design Option (Alternatives D2E and D3)	360	430
130th (*Preferred Alternative D2A* and Alternatives D2E and D3)	320	730
Overlake Village (*Preferred Alternative D2A*, D2A - NE 24th Design Option, and Alternatives D2E, D3, and D5)	220	500
Overlake Transit Center (All Segment D Alternatives)	730	1,120
Segment E		
Redmond Town Center (Alternatives E1 and E4 and E2 – Redmond Transit Center Design Option)	280	320
SE Redmond (*Preferred Alternative E2* and Alternatives E1 and E4)	70	70
Downtown Redmond (*Preferred Alternative E2*)	320	380
Redmond Transit Center (E2 – Redmond Transit Center Design Option)	110	140

[a] Pedestrian and bicycle trips reported for the alternative with the highest ridership.
[b] Trips include both boarding and alighting (exiting).

Although the East Link Project would substantially increase the number of pedestrians in and around the stations, sidewalks and intersection crossings throughout the study area were shown to operate at pedestrian LOS C or better with both the No Build Alternative and East Link. LOS C or better means that there is enough spacing between pedestrians on the sidewalk so that they are able to walk freely at their own speed, with an ability to cross paths without potential collisions with other pedestrians. The pedestrian location in the study area that is expected to operate at LOS C is the 108th Avenue NE and NE 6th Street intersection near the Bellevue Transit Center. The pedestrian LOS at all other locations is expected to operate at LOS B or better.

The following subsections describe the pedestrian and bicycle circulation and conditions by segment during East Link operation. Impacts during construction are also addressed.

3.7.3.1 Segment A, *Preferred Interstate 90 Alternative (A1)*

Pedestrian Circulation

With the project, during the PM peak period, the pedestrian activity at the Rainier Station would be split evenly by year 2030 between people boarding and alighting (exiting) light rail and would be a little less than half of the total person trips at this station. Most of these trips would likely be destined for the surrounding residential neighborhoods, which constitute close to 70 percent of the surrounding land uses, during the PM peak period. Some trips might also be destined for the surrounding commercial and retail land uses along Rainier Avenue South. Overcrowding on sidewalks or at crosswalks is not expected as a result of the activity in the station area.

Pedestrian and bicycle connectivity to the I-90 Lid Park and I-90 Trail from Rainier Station is provided by the midblock crosswalk on 23rd Avenue South. Existing pedestrian access points to the I-90 Regional Trail from South Irving Street would not be affected. Crosswalks at the Rainier Station and the I-90 ramp areas would be maintained and walking distances surrounding the station would not change from existing conditions. Adding wayfinding signage along Rainier Avenue South would help pedestrians navigate through the I-90 ramp area as there are long distances between crosswalks. Nearby school walk routes along local and collector streets would not likely be affected because bus routes serving the Rainier Station would not use these residential local and collector streets.

At the Mercer Island Station, the PM peak-period activity would be split evenly between people boarding and alighting light rail, indicating there would be people destined to the surrounding residential areas and people boarding from the commercial land uses at Mercer Island Town Center.

The access to the Mercer Island Station would be located along 80th Avenue SE. If the passenger drop-off/pick-up area is located along 77th Avenue SE, station access would also be provided along this street. If the passenger drop-off/pick-up area is not located along 77th Avenue SE, then it would remain in the Mercer Island Park-and-Ride lot. An additional station access is being evaluated that would provide a pedestrian bridge extending over eastbound I-90, improving station access to and from the Mercer Island Town Center. About 25 percent of the riders at the station would be expected to use this bridge during the 3-hour peak period. Because *Preferred Alternative A1* is located on I-90, walking distances, sidewalks, and crosswalks on the arterial streets are expected to remain similar to no-build conditions. Overcrowding on sidewalks is not expected near the Mercer Island Station.

School walk routes are not present within walking distance of the Mercer Island Station.

Bicycle Circulation

The proposed bicycle facilities at the Segment A stations are shown in Table 7-6 in Section 7 of the *Transportation Technical Report* (Appendix H1).

The future bicycle circulation on arterial streets surrounding the Rainier and Mercer Island stations would remain similar to existing conditions with and without the project.

With East Link, new access points to the I-90 Trail at the 23rd Avenue South entrance to Rainier Station would be created, increasing the transferability between transit and nonmotorized modes at this location and likely resulting in increased recreational or commuter bicycle activity surrounding the station.

On Mercer Island, locally designated bicycle routes are present on N Mercer Way, 77th Avenue SE, and 80th Avenue SE. Bicycle circulation surrounding the Mercer Island Station would be similar to existing and no-build conditions.

There is no expected change in bicycle circulation along I-90 with the East Link Project, although an increased number of bicycle commuters transferring to and from light rail can be expected because both stations are also conveniently located close to the I-90 Multiuse Regional Trail. Bicycle connection to the I-90 Regional Trail from the Rainier Station would be located at the 23rd Avenue South station entrance, where bicyclists can access the I-90 Lid Park and follow the I-90 Multiuse Regional Trail to the Mt. Baker bicycle and pedestrian tunnel.

3.7.3.2 Segment B

Pedestrian Circulation

Preferred 112th SE Modified Alternative (B2M)

With light rail, most trips at the South Bellevue Station with *Preferred Alternative B2M* would consist of people making transfers among different motorized modes (i.e., automobile or bus); therefore, most pedestrian activity at the South Bellevue Station would occur within the station and park-and-ride lot areas. Much of the land use surrounding the station is a combination of residential and recreational uses. Generally, the pedestrian circulation between the South Bellevue Station and the surrounding neighborhoods is disconnected because of the uphill terrain west of the station. Pedestrian circulation and safety surrounding the South Bellevue Station would improve compared with existing conditions with City of Bellevue's planned sidewalk improvements on 108th and 113th Avenues SE. In addition, the East Link project would not preclude any future improvements planned along Bellevue Way SE.

With *Preferred Alternative B2M*, connecting to either *Preferred Alternative C9T* or *C11A*, a pedestrian and bicycle access to Lincoln Plaza on the east side of 112th Avenue SE would be closed. Alternative access would be available within 300 feet of the existing driveway on SE 6th Street. An option with *Preferred Alternative B2M* connecting to *Preferred Alternative C9T* would close the east approach at SE 15th Street to the Bellefield Office Park. This closure would recirculate pedestrians entering or exiting the office park to the intersection of 114th Avenue SE and SE 8th Street.

Most of the estimated PM peak-period person trips at the SE 8th Station with *Preferred Alternative B2M* connecting to *Preferred Alternative C9T* would consist of pedestrians accessing the station from the surrounding office parks or the South Bellevue neighborhoods. Similar to the other stations in South Bellevue, the SE 8th Station presents longer walking distances because the average block length surrounding this station is longer than other segments. Pedestrian circulation and safety surrounding the SE 8th Station would improve compared with existing conditions with planned sidewalk improvements on SE 8th Street. Access to the at-grade SE 8th Station would be improved with a new crosswalk on the north leg of SE 8th Street.

Overcrowding on sidewalks near the South Bellevue and SE 8th Stations is not expected with *Preferred Alternative B2M*. Crosswalks would be maintained at signalized intersections; therefore, new midblock pedestrian crossings would not be needed within Segment B.

Road widening at intersections related to the at-grade median profile of the *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* would cause increases in walking distances and wait times at crosswalks along 112th Avenue SE.

Other Segment B Alternatives

For Alternatives B2A, B2E, B3, and B3 – 114th Extension Design Option, pedestrian access and circulation at the South Bellevue Station would be similar to conditions under *Preferred Alternative B2M*. The at-grade South Bellevue Station in Alternative B1 would require an increase in the crossing times for pedestrians to walk safely across Bellevue Way at the South Bellevue Station (and throughout the segment).

With Alternative B7, pedestrian facilities would not be affected because most of this alternative is outside the roadway right-of-way. At the 118th Station with Alternative B7, most transit users would consist of riders transferring between light rail and other motorized modes, so most of the pedestrian circulation would occur within the station area. The proximity of I-405 and lack of residential land use immediately surrounding the station do not encourage walk routes. Therefore, substantial pedestrian activity beyond the immediate station area is not expected except to the commercial land uses along SE 8th Street. Pedestrian circulation and safety surrounding the 118th SE Station would improve with planned sidewalk improvements on 114th and 118th Avenues SE at locations immediately surrounding the stations, although crosswalks are not presently provided at the station site, limiting pedestrian mobility.

The existing crosswalk locations would not change with any of the Segment B alternatives except for the new crosswalk on the north leg of 112th Avenue SE and SE 8th Street to improve pedestrian access to the SE 8th Station.

East Link is not expected to affect the Enatai Elementary School walk route.

Bicycle Circulation

Bicycle circulation within Segment B is likely to improve in the no-build condition (compared to existing conditions) with planned improvements along 108th Avenue SE, Bellevue Way, 112th Avenue SE, SE 8th Street, 114th Avenue SE, and the former BNSF Railway. The City of Bellevue 2009 *Pedestrian and Bicycle Transportation Plan Report* identifies future connections between the I-90 Trail and other existing regional and local trails that might increase the number of trail users (City of Bellevue, 2009).

The proposed BNSF Railway Trail, a major multiuse trail, would follow the existing BNSF Railway corridor located along the easternmost boundary of Segment B, proceed through Segments C and D, and terminate in Segment E where it would connect with the East Lake Sammamish Trail. Sound Transit is currently coordinating with the Port of Seattle and King County to cooperatively plan the future trail, possibly including passenger rail and light rail in the same right-of-way while maintaining the ability to provide future freight use.

In general, bicycle circulation with the project would remain similar to the no-build conditions. Bicycle storage and wayfinding at Segment B stations would be provided. Refer to Table 7-9 in Section 7 of the *Transportation Technical Report* (Appendix H1) for the proposed bicycle facilities at the Segment B stations.

Preferred 112th SE Modified Alternative (B2M)
With *Preferred Alternative B2M*, the South Bellevue station would be located near the Mercer Slough where bicyclists could connect to the I-90 Trail and the 118th Avenue SE Regional Multiuse Trail. As a result, an increase in bicycle activity on these trails would likely occur.

Impacts on trails in Segment B would include acquiring right-of-way along 112th Avenue SE for the *Preferred Alternative B2M*. This alternative would require using narrow portions of the Mercer Slough Park's western boundary, requiring a portion of the Heritage Trail that is within the Mercer Slough to be relocated. Impacts on the I-90 Trail at the I-405 interchange are not expected with the *Preferred Alternative B2M*.

A pedestrian and bicycle access to Lincoln Plaza on the east side of 112th Avenue SE would be closed with *Preferred Alternative B2M*. Alternative access would be available within 300 feet on SE 6th Street. An option with *Preferred Alternative B2M* connecting to *Preferred Alternative C9T* would close the east approach at SE 15th Street to the Bellefield Office Park. This closure would recirculate bicyclists entering or exiting the Bellefield Office Park to the intersection of 114th Avenue SE and SE 8th Street. This would affect bicycle mobility between the Bellefield Office Park and areas to the south.

Other Segment B Alternatives
Similar to *Preferred Alternative B2M*, impacts to trails along Bellevue Way and near the South Bellevue Station would occur under Alternatives B1, B2A, B2E, B3, and B3 – 114th Design Option. Alternatives B2A and B2E would close the pedestrian and bicycle access to the Lincoln Plaza on the east side of 112th Avenue SE, similar to *Preferred Alternative B2M.*

Under Alternative B7, existing bicycle access to the east side of the Mercer Slough Nature Park along 118th Avenue SE would be maintained and would connect to the Mercer Slough Trails and I-90 Regional Trail.

3.7.3.3 Segment C

The East Link Project would serve Downtown Bellevue, one of the major business and employment centers in the Puget Sound region. Compared to other segments, pedestrian activity is much higher in Downtown Bellevue. To provide adequate sidewalk circulation, future development projects or planned city capital improvements are expected to fill in the identified missing sidewalk segments within the downtown area, although nearly all the streets in Downtown Bellevue already provide continuous sidewalks on both sides of the street. In general, pedestrian circulation conditions under any Segment C alternative would not differ substantially except for the changes described in the following subsections. Street widening would generally be minimal due to right-of-way constraints; therefore, pedestrian crossing distances are generally similar to no-build conditions.

As shown in Exhibit 3-27, among the proposed stations in Segment C, the light rail stations located closer to the existing Bellevue Transit Center would be expected to attract more riders because those stations would better serve Downtown Bellevue as a result of their proximity to denser employment and residential areas. The farther east the stations are located from Downtown Bellevue, the less pedestrian activity would be expected. Because the Ashwood/Hospital Station would be within walking distance from both Overlake Hospital and Downtown Bellevue, it would have more pedestrian activity in connection with downtown than the Hospital Station; however, the Hospital Station would have the potential for higher pedestrian activity in connection with the planned redevelopment of the Wilburton area. These trends are discussed in Section 3.4.3.6, Light Rail Ridership.

Pedestrian Circulation

Preferred 108th NE At-Grade Alternative (C11A)
Preferred Alternative C11A would not impact pedestrian facilities. The midblock crossing on 108th Avenue NE between NE 2nd and 4th Streets would be maintained and signalized to provide a safe crossing. At the 112th Avenue SE and SE 6th Street intersection, pedestrians and bicyclists would cross the at-grade light rail tracks on the west side of 112th Avenue SE.

Exhibit 3-27 **Pedestrian Walking Areas by Stations in Downtown Bellevue and Bel-Red Area Segments C and D**

East Link Project

Similarly, pedestrians would cross the at-grade light rail tracks on the southeast corner of Main Street and 108th Avenue. Features such as fencing, signing, pavement markings, warning bells, and traffic signals would be provided at these locations for pedestrian safety.

Although this alternative is an at-grade profile, street widening would be minimal because of right-of-way constraints; therefore, relatively small changes to pedestrian crossing distances are expected. However, some increase in crosswalk distances would occur at Main Street and 108th Avenue NE and along NE 6th Street to accommodate the light rail track alignment.

The 108th Station location with *Preferred Alternative C11A* would not affect pedestrian facilities because it is located off-street, south of Main Street. This station location would be convenient to a higher percentage of the Downtown Bellevue residents and employment centers compared to the East Main Station location.

The Bellevue Transit Center Station area would have the highest number of PM peak-period pedestrian trips compared to other East Link stations, as close to 3,800 pedestrians and bicyclists would use this station in 2030. This would be about 60 percent of the estimated total PM peak-period person trips at this station. Most pedestrian activity at this station would be people boarding light rail in the PM peak period, mainly people walking from the surrounding office and commercial land uses. This degree of activity would be consistent with an urban downtown environment that is expected to become denser in the future.

Major pedestrian crossings and sidewalks near the Bellevue Transit Center Station area for *Preferred Alternative C11A* would provide sufficient pedestrian space, although sidewalks and intersections connecting to entrances to the Bellevue Transit Center Station on 108th and 110th Avenues NE would experience some pedestrian crowding during peak periods. In the no-build condition, the sidewalks near the Bellevue Transit Center would degrade from existing conditions to LOS C but would continue to operate well as pedestrian activity is expected to continue moving freely. With East Link, the pedestrian LOS near the Bellevue Transit Center would continue to operate no worse than LOS C. Any crowding would generally be contained within the station near the platforms. The location of the Bellevue Transit Center Station with *Preferred Alternative C11A* would be the most convenient for bus connections and would serve the majority of downtown Bellevue residents and employment centers.

Preferred Alternative C11A also would serve the Hospital Station located north of NE 8th Street, east of 116th Avenue NE. The location of the Hospital Station is near the Overlake Hospital area and other retail and commercial land uses. Pedestrian trips are estimated to comprise about 60 percent of the future PM peak-period person trips and primarily include people leaving Overlake Hospital and the surrounding office, retail, and commercial areas and boarding light rail. This station's location would also serve the Wilburton neighborhood, where future nonmotorized improvements are planned by others near the station to improve the connectivity for pedestrians and bicyclists navigating along NE 8th Street (sidewalk improvements) and along the former BNSF Railway corridor (BNSF Railway regional multiuse trail).

With connections to Alternatives B3, B7, or B3 – 114th Design Option, *Preferred Alternative C11A* would serve the East Main Station. Pedestrian trips are estimated to comprise close to 70 percent of the future PM peak-period person trips, with most of these being people boarding light rail. These pedestrians are expected to originate from the adjacent residential and commercial areas. Topography constraints to the west into central downtown Bellevue may limit pedestrian activity.

Preferred 110th NE Tunnel Alternative (C9T)

Because *Preferred Alternative C9T* profiles would be mostly elevated and tunnel north of Main Street, there would be minimal impacts on pedestrian circulation. Impacts on crosswalks are not expected with the *Preferred Alternative C9T* except along NE 6th Street, which would be widened to accommodate the tunnel portal and, therefore, would require slightly longer distances for pedestrians to cross. At the at-grade light rail crossing at the SE 6th Street and 112th Avenue SE intersection, pedestrians and bicyclists would cross over the tracks on both sides of 112th Avenue SE. Features such as fencing, signing, pavement markings, warning bells, and traffic signals would be provided for pedestrian safety.

Major pedestrian crossings and sidewalks near the Bellevue Transit Center Station area for *Preferred Alternative C9T* provide sufficient pedestrian space, although sidewalks and intersections connecting to entrances to the Bellevue Transit Center Station along 110th Avenue NE would experience some pedestrian crowding during peak periods. Pedestrian access between Bellevue Transit Center Station and the Bellevue Transit Center would be through the northern station entrance on the north side of NE 4th Street with a crossing at NE 6th Street and 110th Avenue NE to access the Bellevue Transit Center bus platform. The design option to include an additional northern entrance of the Bellevue Transit Center Station to the west side of 110th Avenue NE would provide a more direct bus transfer connection between the Bellevue Transit Center Station and the Bellevue Transit Center bus platforms.

Preferred Alternative C9T would also serve the Hospital Station. Pedestrian activity in and around this station would be similar to *Preferred Alternative C11A*.

With the option to connect to Alternative B3, B3 – 114th Design Option, or B7, *Preferred Alternative C9T* would serve the East Main Station, and nonmotorized activity would be similar to *Preferred Alternative C11A*. Nonmotorized activity for the East Main Street Station design option under *Preferred Alternative C9T* would be similar to a connection with Alternative B3, B3 - 114th Extension Design Option, or B7 that have an East Main Station.

Other Segment C Alternatives
The Bellevue Way Tunnel Alternative (C1T) is the only alternative that would include the underground Old Bellevue Station. Much of the pedestrian activity at the Old Bellevue Station would be a result of neighboring commercial and residential land uses surrounding the station. The location of this station is expected to capture a portion of pedestrian activity on the fringe of Downtown Bellevue that would otherwise require farther walking distance to the Bellevue Transit Center.

Alternatives C2T, C3T, C4A, C7E, C8E, and C9A would serve the East Main Station, depending on the connections from Segment B (Alternative B3, B3 – 114th Design Option, or B7). Pedestrian activity at this station would be similar to that of *Preferred Alternative C9T* (with connections to Alternatives B3, B3 – 114th Design Option, and B7). Alternative C14E would not include an East Main Station.

Pedestrian circulation at the Bellevue Transit Center Station for Alternatives C1T, C2T, and C3T would be similar to that of the *Preferred Alternative C9T,* although Alternatives C1T and C2T would have a more direct connection to the Bellevue Transit Center. At-grade Alternatives C4A and C9A would have slightly different pedestrian circulation and access at the Bellevue Transit Center Station than *Preferred Alternative C11A*. While both of these alternatives are within one block of the Bellevue Transit Center, the station is not directly integrated with the Bellevue Transit Center; therefore, connections with other transit services are not as convenient as with *Preferred Alternative C11A*. Additionally, Alternative C4A includes two stations, one on 108th Avenue NE and one on 110th Avenue NE, as track is only provided in one direction along each of these streets. Pedestrian access between Bellevue Transit Center Station and the Bellevue Transit Center for Alternative C9A would be through the western station entrance located at NE 6th Street and 110th Avenue NE, with one crossing at NE 6th Street and 110th Avenue NE to connect the station with the bus platforms. With any of these alternatives, major pedestrian crossings and sidewalks near the Bellevue Transit Center Station would experience some pedestrian crowding during peak periods. Alternative C8E would have similar pedestrian circulation at the Bellevue Transit Center Station under *Preferred Alternative C9T.* Although it is an elevated station and Alternative C9T is a tunnel station, both would have similar pedestrian effects.

Alternatives C7E and C14E are both elevated profiles outside the downtown core; therefore, minimal impacts to the pedestrian circulation and connectivity in downtown Bellevue are expected. To provide a connection between the Bellevue Transit Center and the Bellevue Transit Center Station (along 112th Avenue NE [C7E] or 114th Avenue NE [C14E]) an elevated and covered moving walkway would be constructed as part of these two alternatives. With the Bellevue Transit Center station location further east than other Segment C alternatives, the pedestrian connections would not be as convenient and the distances to many locations in Downtown Bellevue would be greater with these two alternatives.

Most pedestrian trips during the PM peak-period at the Ashwood/Hospital Station would consist of people leaving Overlake Hospital and the surrounding office and commercial areas. Pedestrian access to this station would be provided on both sides of I-405. The Hospital Station would have a similar amount of pedestrian activity as the Ashwood/Hospital Station because they both capture the land uses along 116th Avenue NE. Alternatives C3T, C4A, C7E, and C8E would serve the Ashwood/Hospital Station, while Alternatives C1T, C2T, C9A, and C14E would serve the Hospital Station. Pedestrian activity at the Hospital Station for Alternatives C1T, C2T, C9A, and C14E would be similar to *Preferred Alternatives C11A* and *C9T*.

Similar to *Preferred Alternative C11A*, most of Alternatives C4A, C8E, and C9A would be within the roadway right-of-way in Downtown Bellevue. Even so, these alternatives would generally not increase the pedestrian crossing distances at intersections because roadway widening is constrained by the available right-of-way. Crosswalk locations along 108th and 110th Avenues NE with the Couplet Alternative (C4A) would remain but would require signal phasing adjustments. Similar to *Preferred Alternative C9T*, crosswalk impacts are not expected with the tunnel alternatives (C1T, C2T, and C3T) because these alternatives would be mainly underground in Downtown Bellevue. Alternatives C1T, C2T, and C9A would become elevated on NE 6th Street, east of 110th Avenue NE, and similar to *Preferred Alternatives C11A* and *C9T*, some roadway widening is proposed. This would lengthen the pedestrian crossing distances on this street. Alternatives C7E and C14E would not impact pedestrian crossings because most of the alternative would be outside the roadway right-of-way.

The school walk route along 108th Avenue SE is not expected to be affected by any of the Segment C alternatives because it is located south of Main Street.

Bicycle Circulation

With East Link, bicycle circulation through Downtown Bellevue would remain similar to existing conditions and the No Build Alternative. Currently, nearly all arterial streets in the downtown area are designated bicycle routes and the City of Bellevue plans to provide bicycle improvements along 112th Avenue NE north of NE 12th Street and along 108th Avenue NE in Downtown Bellevue in the future.

Bicycle storage and wayfinding at Segment C stations would be provided. Refer to Table 7-11 in Section 7 of the *Transportation Technical Report* (Appendix H1) for the proposed bicycle facilities at the Segment C stations.

Preferred 108th NE At-Grade Alternative (C11A)

Preferred Alternative C11A would not likely affect bicycle facilities as a wide vehicle lane in both directions would be provided on 108th Avenue NE to accommodate bicyclists. Additionally, the location of the 108th, Bellevue Transit Center, and Hospital stations would not likely affect bicycle facilities. At the at-grade crossings, the light rail tracks would be designed so that bicyclists along designated bicycle routes cross the light rail tracks at a perpendicular angle (to the extent possible) for bicyclist safety.

With a connection to Alternative B3, B7, or B3 - 114th Design Option, *Preferred Alternative C11A* would not affect bicycle facilities along 112th Avenue SE.

Preferred 110th NE Tunnel Alternative (C9T)

Preferred Alternative C9T is mostly comprised of elevated and tunnel profiles north of Main Street and an at-grade profile south of Main Street, thereby resulting in minimal bicycle circulation impacts. At the at-grade crossing at SE 6th Street and 112th Avenue SE, bicycle routes would be designed so that bicyclists cross the light rail tracks at a perpendicular angle for bicyclist safety.

With a connection to Alternatives B3, B7, or B3 - 114th Design Option, *Preferred Alternative C9T* would not affect bicycle facilities along 112th Avenue SE.

Other Segment C Alternatives

The other Segment C alternatives with elevated profiles (Alternatives C7E, C8E, and C14E) and tunnel profiles (Alternatives C1T, C2T, and C3T) would have minimal impacts on downtown bicycle circulation. Crosswalk access for bicyclists would operate under the same conditions as pedestrian access previously described.

Alternative C4A would change circulation patterns for bicyclists traveling on 108th Avenue NE and 110th Avenue NE by converting these streets to a one-way couplet. This could create some recirculation of bicycle activity because cyclists would not have the ability for two-way travel on these streets. The side-track alignment Alternative C4A creates the potential for bicyclists to turn across the light rail tracks.

Alternative C9A would not affect planned bicycle facilities, similar to *Preferred Alternative C11A*.

With any of the Segment C alternatives that include a connection to Alternative B3, B7, or B3 - 114th Design Option, similar effects on bicycle facilities along 112th Avenue SE would occur as with the *Preferred Alternative C11A*.

3.7.3.4 Segment D

In the Bel-Red area, the pedestrian and bicycle facilities planned as part of the City of Bellevue's Bel-Red Subarea Plan would support the East Link project. Implementing the Bel-Red Subarea Plan would improve the pedestrian and bicycle connections in this area, as the planned high-density, transit-oriented land uses would be expected to substantially increase the pedestrian and bicycle activity.

Pedestrian Circulation

Preferred NE 16th At-Grade Alternative (D2A)

In the Bel-Red area, the 120th and 130th stations would support the pedestrian facilities planned as part of the transportation and land use projects in the City of Bellevue's Bel-Red Subarea Plan. Implementing the Bel-Red Subarea Plan would improve the pedestrian connections near the station areas.

More than half the transit users at the 120th Station during the PM peak period would be walk and bicycle trips that would likely originate from the surrounding planned commercial, retail, and office land uses.

The D2A - 120th At-Grade Design Option would provide a slightly more convenient pedestrian and bicycle access to the street system because it is at-grade compared with the *Preferred Alternative D2A* retained-cut 120th Station.

Pedestrian activity would be higher at the 130th Station, and most of the trips would consist of pedestrians or bicyclists, with most boarding light rail during the PM peak period. Many of the light rail boardings would likely originate from nearby commercial, retail, and office parks planned as part of the redevelopment strategy in the Bel-Red Subarea Plan.

The 120th Station and 130th Station are within moderately close walking distance of each other. This is illustrated in Exhibit 3-27. Pedestrians would access the station that is closest to their walk route. The western edge of the 120th Station walking area is constrained by terrain and presents a barrier to effectively connect with this station. These factors would likely be the cause of the lower level of pedestrian activity at the 120th Station.

At the Overlake Village Station, the future PM peak volumes of pedestrians would primarily consist of riders transferring between light rail and other modes. Many of the pedestrian trips would originate from nearby office park, commercial, and mixed land uses. For improved bicycle and pedestrian connections between the Overlake Village Station (associated with *Preferred Alternative D2A*) and the commercial properties north of SR 520, the City of Redmond could build a new nonmotorized, multiuse bridge over SR 520.

At the Overlake Transit Center Station, about two-thirds of the transit riders would transfer among modes and the remaining third would be pedestrians and bicyclists. Most of the pedestrian activity at this station in the PM peak period is expected to consist of commuters coming from large employment centers near the station and boarding light rail. To help facilitate pedestrian movements across 156th Avenue NE, the project would provide another crosswalk at the intersection of NE 38th Street and 156th Avenue NE. For improved bicycle and pedestrian connections between the Overlake Transit Center Station and the properties west of SR 520, a new nonmotorized, multiuse bridge over SR 520 could be constructed by others.

Currently, there are limited sidewalks and crosswalks on NE 16th Street between 132nd Street and 136th Place NE and on 136th Place NE between NE 16th and NE 20th Streets. The *Preferred Alternative D2A* would provide sidewalks on both streets, and crosswalks would be located at the NE 16th Street and 132nd Avenue NE and at the NE 16th Street and 136th Place NE intersections. Increases in the pedestrian crossing distance would occur along NE 16th Street and 136th Place NE. Additionally, planned improvements included in the Bel-Red Subarea Plan would provide sidewalks and crosswalks near both 120th and 130th stations with the NE 15th/16th Street extension project being designed by the City of Bellevue.

Sidewalks at the intersections nearest to all station entrances for *Preferred Alternative D2A* would operate at LOS A in the no-build and build conditions, indicating that pedestrian flows to and from the station would occur without crowding (refer to the *Transportation Technical Report* [Appendix H1] for a more detailed discussion of pedestrian LOS).

There would be no impacts on any school walk routes with the *Preferred Alternative D2A*.

Other Segment D Alternatives

Similar to the *Preferred Alternative D2A*, the pedestrian facilities planned as part of the City of Bellevue's Bel-Red Subarea Plan would support and connect to the 120th and 130th stations for Alternatives D2E and D3. Because neither the 120th Station nor 130th Station is considered with Alternative D5, there would be no nonmotorized benefits to East Link Project with the Bel-Red Subarea Plan.

The PM peak-period pedestrian trips generated at the 120th Station for Alternatives D2E and D3 would be similar to the trips generated at the 120th Station with the *Preferred Alternative D2A*. The 130th Station pedestrian trips for Alternatives D2E and D3 would be similar to the 130th Station trips generated with *Preferred Alternative D2A*.

Pedestrian circulation to and from the private properties west of 152nd Avenue NE, near the Overlake Village Station, would be relocated to 151st Avenue NE with Alternatives D2A – NE 24th Design Option, D2E, and D5 as these alternatives prohibit pedestrians from crossing the tracks. This would create some out-of-direction travel for pedestrians. Alternative D3 would provide an additional crosswalk north of the Overlake Village Station at NE 26th Street to accommodate pedestrian movements to and from the station platform.

Pedestrian circulation at the Overlake Transit Center for Alternatives D2E, D3, and D5 is similar to the conditions for *Preferred Alternative D2A*.

Similar to *Preferred Alternative D2A*, sidewalks would be provided on NE 16th Street between 132nd Street and 136th Place NE and on 136th Place NE between NE 16th and NE 20th Streets for Alternatives D2E and D3. Increases in pedestrian crossing distances would occur at the signalized intersections along NE 16th Street and 136th Place NE (similar to *Preferred Alternative D2A*) and at the NE 24th Street and 152nd Avenue NE intersection with Alternatives D2E and D3. In addition, with Alternative D3, increases in pedestrian crossing distances would occur along NE 20th Street between 136th Place NE and 152nd Avenue NE.

Similar to *Preferred Alternative D2A*, sidewalks at the intersections nearest to all the Alternative D2E, D3, and D5, station entrances would operate at LOS A in the no-build and build conditions (see Table F-4 in Appendix F of the *Transportation Technical Report* [Appendix H1]).

There would be no impacts on any school walk routes with Alternatives D2E, D3, and D5.

Bicycle Circulation

The stations in Segment D would have minimal to no impacts on existing bicycle circulation. All arterial streets are part of a designated bicycle route network; however, bicycle circulation is currently limited because designated bicycle lanes are not present on arterial streets. In the future, substantial bicycle facility improvements are included in the City of Bellevue's Bel-Red Subarea Plan. These improvements would support and connect the 120th and 130th stations.

Bicycle storage and wayfinding at Segment D stations would be provided. The proposed bicycle facilities at the Segment D stations are shown in Table 7-13 in Section 7 of the *Transportation Technical Report* (Appendix H1).

Preferred NE 16th At-Grade Alternative (D2A)

Similar to the pedestrian circulation, bicycle facilities planned as part of the City of Bellevue's Bel-Red Subarea Plan would support and connect to the 120th and 130th stations. Both of these stations would be close to the SR 520 Multiuse Regional Trail; however, trail access would be limited to public park areas, and direct access from arterial streets would be constrained by terrain and private properties.

Bicycle circulation conditions near the Overlake Village Station and Overlake Transit Center Station would be similar to existing conditions. The City of Redmond could construct a new nonmotorized, multiuse bridge over SR 520 to improve nonmotorized connections between the Overlake Village Station (associated with *Preferred Alternative D2A*) and the commercial properties north of SR 520. Additionally, improved bicycle and pedestrian connections between the Overlake Transit Center Station and the properties west of SR 520, could occur if a new nonmotorized, multiuse bridge over SR 520 were built by others.

Even though the Overlake Village and Overlake Transit Center Stations are located close to the SR 520 Regional Multiuse Trail, access between the trail and these stations would be indirect as trail users would need to cross SR 520 unless the nonmotorized bridges proposed by others were to be built.

Other Segment D Alternatives

All other Segment D alternatives except Alternative D5 (D2A – 120th and 24th Design Options, D2E, and D3) would have bicycle impacts at the 120th and 130th stations similar to those of *Preferred Alternative D2A*.

Similar to the pedestrian circulation, because neither 120th Station nor 130th Station is considered with Alternative D5, there would be no nonmotorized benefits with this alternative in conjunction with the Bel-Red Subarea Plan.

All other Segment D alternatives would have bicycle impacts at the Overlake Village and Overlake Transit Center similar to those of the *Preferred Alternative D2A*.

3.7.3.5 Segment E

Pedestrian and bicycle circulation and connectivity within Segment E would be improved with development projects or planned city capital improvements.

Pedestrian Circulation

Preferred Marymoor Alternative (E2)

Preferred Alternative Marymoor (E2) would be the only Segment E alternative that would serve the at-grade Downtown Redmond Station. This station would have the highest PM peak-period bicycle and pedestrian trips compared with the other Segment E stations as it surrounds major commercial and retail areas. This is indicated in Table 3-32. If light rail riders were to park at the Redmond Transit Center, then they would need to cross SR 202 to access this station. Most light rail riders at this station would likely make bus transfers or walk to and from the surrounding commercial and retail areas.

Preferred Alternative E2 would also serve the SE Redmond Station. The pedestrian activity at the SE Redmond Station would primarily be within the facility and occur at the park-and-ride area as a result of many people transferring from light rail to autos. This travel pattern would be expected because the surrounding land uses include industrial and commercial buildings. Pedestrian circulation near this station would also be limited by wide, multilane arterials with heavy traffic volumes and by the proximity to SR 520, which is a physical barrier to travel to and from Downtown Redmond.

The future BNSF Railway regional multiuse trail would provide pedestrian access to and from both of these stations. With *Preferred Alternative E2*, crossings at 161st, 164th, 166th, and 170th Avenues NE and NE Leary Way would be maintained. Gates would be installed at at-grade intersections and at driveways along the BNSF Railway corridor through Downtown Redmond. Pedestrian crosswalks at these locations would be maintained.

Other Segment E Alternatives

The Redmond Way Alternative (E1), E2 - Redmond Transit Center Design Option, and Leary Way Alternative (E4) would serve the at-grade Redmond Town Center Station. Most light rail pedestrian activity at the Redmond Town Center Station would be similar to the Downtown Redmond Station with *Preferred Alternative E2*. Close to one-third of the riders at the Redmond Town Center Station would likely walk to and from the surrounding commercial and retail areas.

With the Alternative E2 – Redmond Transit Center Design Option, while 35 percent of the future PM peak-period person trips at the Redmond Transit Center Station would be pedestrians or bicyclists there are less than 150 walk and bike trips forecasted at this station. This is likely because of the nearby Redmond Town Center Station. The highest pedestrian activity at the Redmond Transit Center Station would occur within the station at the park-and-ride lot, as many riders would be transferring between modes.

Pedestrian circulation and connectivity at the SE Redmond Station for Alternatives E1 and E4 would be similar to those discussed for *Preferred Alternative E2*.

In terms of pedestrian crosswalk conditions, minimal increases in walking distances are expected only with the Alternative E2 - Redmond Transit Center Design Option, along 161st Avenue NE, from Cleveland Street to NE 85th Street.

Similar to *Preferred Alternative E2*, Alternatives E1 and E4 would use the former BNSF Railway right-of-way. Both of these alternatives would have street crossings at 164th, 166th, and 170th Avenues NE. Alternative E1 would have additional street crossings at 161st Avenue NE and NE Leary Way, similar to *Preferred Alternative E2*. Alternative E4 would have additional crossings at Bear Creek Parkway and NE 76th Street. Pedestrian crosswalks at these locations would be maintained. To provide safe vehicle and pedestrian movements across the tracks, gates would be installed at at-grade intersections and driveways along the corridor through Downtown Redmond. At the Redmond Transit Center, pedestrian access to the station platform would occur at the crosswalks at NE 80th and 83rd streets.

The recommended school walk route for Redmond Elementary School consists of collector and local streets in residential areas of Segment E, and impacts on the walk route are not expected as none of the East Link alternatives would cross these routes.

Bicycle Circulation

With the East Link Project, circulation for bicyclists in Segment E would likely not differ greatly from circulation under the No Build Alternative. Future bicycle improvement projects would enhance bicycle circulation by improving access to Marymoor Park and the Sammamish Regional Multiuse Trail system. These bicycle facilities are close to the proposed stations; however, direct access to them would be hindered by SR 520, especially from the Redmond Town Center.

Bicycle storage and wayfinding would be provided at Segment E stations. The proposed bicycle facilities at the Segment E stations are shown in Table 7-15 in Section 7 of the *Transportation Technical Report* (Appendix H1).

Preferred Marymoor Alternative (E2)

The *Preferred Alternative E2* would not preclude the potential development of a multiuse trail located along the former BNSF Railway tracks parallel to light rail tracks. Developing a multiuse trail in this corridor would create a pedestrian and bicycle connection between the Bear Creek Trail and Lake Sammamish.. The trail would be directly accessible from the SE Redmond Station and Downtown Redmond Station and allow nonmotorized commuters to transfer to light rail.

Other Segment E Alternatives

The bicycle lanes along 161st Avenue NE would be maintained with Alternative E2 – Redmond Transit Center Design Option to ensure nonmotorized connectivity between the Redmond Transit Center Station and the nearby Sammamish Regional Multiuse Trail and proposed multiuse trail located along the former BNSF Railway corridor.

Similar to the *Preferred Alternative E2*, Alternatives E2 – Redmond Transit Center Design Option and E1 and E4 would not preclude the potential multiuse trail located along the former BNSF Railway corridor. The trail would be directly accessible from SE Redmond Station and Redmond Town Center Station and would allow nonmotorized commuters to transfer to light rail.

3.7.3.6 Construction Impacts

Potential construction impacts for pedestrian and bicycle circulation could occur along streets with partial or full closures because these types of construction areas may restrict or provide detour routes for pedestrians and/or bicyclists. Regional multiuse trails might experience some temporary construction impacts due to their proximity to the alternatives. Section 3.6 discusses and Table 3-31 lists the streets with expected closures during construction. Sound Transit would minimize disruptions to the sidewalk or bicycle network and provide detours as practical during construction.

In Bellevue, a number of bicycle facilities are planned as part of the City's future transportation improvement projects within the study area (Exhibits 7-9 through 7-11 in Appendix H1 [*Transportation Technical Report*]). If these projects are completed before light rail construction, then the bicycle lanes and routes that are located within or adjacent to light rail construction areas could be temporarily affected during construction and would be closed or detours would be provided, depending on the type of construction activity. In Segments B, C, D, and E, the potential multiuse trail along the former BNSF Railway corridor would be affected in some areas if constructed prior to East Link.

In Redmond, most arterials are designated as existing bicycle routes or provide bike lanes. Similar to the potential impacts on bicycle facilities in Bellevue, some bicycle facilities in Redmond would be temporarily closed or detours provided during construction.

Segment A, *Preferred Interstate 90 Alternative (A1)*

The portion of the I-90 Multiuse Regional Trail located on the I-90 bridge would not be affected by light rail construction.

Segment B

Preferred 112th SE Modified Alternative (B2M)

Near the I-90 and Bellevue Way interchange, the I-90 Trail could be temporarily affected by construction associated with any of the Segment B alternatives. During construction, temporary trail closures or detours could occur where the trail is close to the I-90 and Bellevue Way ramps, and near the western boundary of the Mercer Slough Nature Park.

During the civil construction period for *Preferred Alternative B2M*, the sidewalk on the eastern side of Bellevue Way SE and 112th Avenue SE would likely close and require detours. A portion of the Periphery Loop Trail would be closed during construction and require detours. Impacts on the trail network within the Mercer Slough Nature Park are not expected.

Other Segment B Alternatives

During the civil construction period along Bellevue Way for Alternatives B1, B2A, B2E, and B3, the sidewalk along Bellevue Way SE and 112th Avenue SE would likely close and require detours similar to *Preferred Alternative B2M*. Impacts on the Periphery Loop Trail and Mercer Slough Nature Park trail network would be similar to *Preferred Alternative B2M*.

The 118th Avenue Regional Multiuse Trail could be temporarily affected near I-90 by construction associated with Alternative B7. Also with construction of Alternative B7, short-term nonmotorized construction impacts would occur with the elevated portion of the Alternative B7 construction along 118th Avenue SE.

Segment C

Preferred 108th NE At-Grade Alternative (C11A)

With the construction of *Preferred Alternative C11A*, sidewalks along 112th Avenue SE, Main Street, 108th Avenue NE, and NE 6th Street would likely remain open on at least one side and, to the extent possible, pedestrian connections would be maintained at intersections. Pedestrian access to buildings would also be maintained.

Preferred 110th NE Tunnel Alternative (C9T)

During construction for the *Preferred Alternative C9T*, sidewalks along 112th Avenue SE, Main Street, 110th Avenue NE, and NE 6th Street would likely remain open on one side during construction. Pedestrian connections would be maintained at intersections to the extent possible. Pedestrian access to buildings would also be maintained.

Other Segment C Alternatives

Civil construction activities with Alternatives C1T, C2T, and C3T would likely close sidewalks on at least one side of the street along the construction route, although pedestrian connections would be maintained, to the extent possible, at intersections. The pedestrian connection along NE 6th Street would be maintained with Alternative C1T and C2T construction either along this route or nearby depending on the construction activity.

During the civil construction period of Alternative C4A, the sidewalk would likely be closed on one side of 108th and 110th Avenues NE and along one side of Main and NE 12th Streets between 108th and 112th Avenues NE.

Alternative C9A would have nonmotorized construction impacts similar to *Preferred Alternative C9T*.

There would be minimal impacts on pedestrians and bicyclists during construction of Alternatives C7E and C14E. The bicycle route along 114th Avenue SE between SE 6th and Main Streets would likely be rerouted along SE 6th Street and 112th Avenue SE during construction of Alternative C14E. Construction associated with Alternative C8E would likely close sidewalks on one side along the construction route of NE 2nd Street, 110th Avenue NE, and NE 12th Street.

Segment D

Civil construction impacts on the SR 520 Multiuse Regional Trail are not expected because the East Link Project does not require widening or realignment of SR 520 and does not require relocation of the trail. The SR 520 trail in Segment D is located along the north side of SR 520, and construction impacts are not foreseen because the alternatives in Segment D are located on the south side of SR 520.

The construction of a pedestrian bridge across SR 520 to the Overlake Village Station with the *Preferred Alternative D2A* and/or to the Overlake Transit Center (all Segment D alternatives) would create short-term lane closures on SR 520.

Preferred NE 16th At-Grade Alternative (D2A)

In Segment D, sidewalk, associated with the construction of the *Preferred Alternative D2A* (and both the D2A – 120th and NE 24th Design Options) would likely remain open on one side of the road along NE 16th Street between 132nd Street and 136th Place NE, and 136th Place NE and the west side of Microsoft Road.

Other Segment D Alternatives

Similar sidewalk closures along NE 16th Street between 132nd Street and 136th Place NE, 136th Place NE, and Microsoft Road would likely occur under Alternatives D2E and D3. Along the proposed NE 15th Street between 120th and 124th Avenues NE, sidewalk closures would be likely under Alternatives D2E and D3.

Sidewalks on one side of 24th Street between 148th Avenue NE and 152nd Avenue NE would likely be closed with Alternative D2A - NE 24th Design Option and Alternative D2E. Alternative D3 would likely have sidewalk closures along NE 20th Street between 136th Place NE and 152nd Avenue NE and along 152nd Avenue NE.

Alternative D5 would likely have sidewalk closures along the west side of 152nd Avenue NE and Microsoft Road.

Segment E

The elevated alternatives in Segment E would cross the Sammamish River Trail, resulting in minor short-term trail detours. Alternative E1 would cross the Bridle Crest Trail and the Bear Creek Trail. Alternative E1 would require minor realignment of the East Lake Sammamish Trail in the area along the former BNSF Railway tracks. With Alternative E2 - Redmond Transit Center Design Option, the sidewalk along 161st Avenue NE would be closed.

3.7.4 Potential Mitigation

No adverse impacts have been identified due to East Link operations and therefore no mitigation to nonmotorized facilities is proposed. As described in Section 3.7.3, Sound Transit would provide pedestrian and bicycle improvements at East Link stations. Sound Transit would work with the local agencies regarding alternatives and stations that are located within the median of roadways so that the most appropriate treatments are provided for safe and effective pedestrian crossings and access. These treatments could include painted crosswalks or signals, street lighting, warning lights or bells, or signage.

During construction, Sound Transit would minimize potential impacts on pedestrian and bicycle facilities by providing detours or clearly delineated facilities within construction areas, such as protected walkways, and notify the public as appropriate. For example, with the sidewalk closed along Bellevue Way SE during the construction of the *Preferred Alternative B2M*, methods to maintain pedestrian access could include the use of a protected walkway adjacent to the construction area or a similar provision.

Multiuse trails that may be affected by construction would generally be kept open for use, but detours would be provided when trails are closed unless they are closed for short durations or in areas where a detour option is not feasible. Public notification efforts would be conducted for temporary trail closures during construction.

3.8 Freight Mobility and Access

3.8.1 Methodology

Truck routes within the study area were identified and analyzed to compare potential impacts on freight movement from the No Build Alternative and the East Link Project. Freight movements were analyzed along I-90, on arterial and local routes, and on railways. Additional truck data and analysis are provided in Appendix H1, *Transportation Technical Report*.

3.8.2 Affected Environment

Truck mobility within the Puget Sound region is largely supported by a system of designated truck routes consisting of freeways and arterial streets that connect major freight destinations. WSDOT has adopted the Freight Goods Transportation System (FGTS), which classifies roadways according to the amount of annual tonnage transported along these roads. All interstates and state routes are designated as truck routes, and each jurisdiction locally determines its designated truck route system on arterial streets according to the FGTS classification. Within the study area, I-90 and I-405 are designated as T-1 freight routes, which indicate that over 10,000,000 gross tons of freight goods are moved every year. SR 520 is classified as a T-2 freight route, indicating between 4,000,000 and 10,000,000 gross tons of freight goods are moved yearly.

Within the East Link study area, there are key freight corridors that serve not only the Puget Sound region but also national and international markets, such as I-90 and I-405. There also are many local truck routes that facilitate the flow of deliveries to local businesses. These transportation corridors are vital to the movement of freight and goods among major transportation hubs such as the Port of Seattle, the Seattle-Tacoma International Airport (Sea-Tac Airport), and other business and consumer destinations. Within the East Link study area, freight goods and services are only transported on roadways, although some of the freight transported on I-90 and the other highways (I-405 and SR 520) in the study area is associated with marine facilities, such as the ports of Tacoma and Seattle.

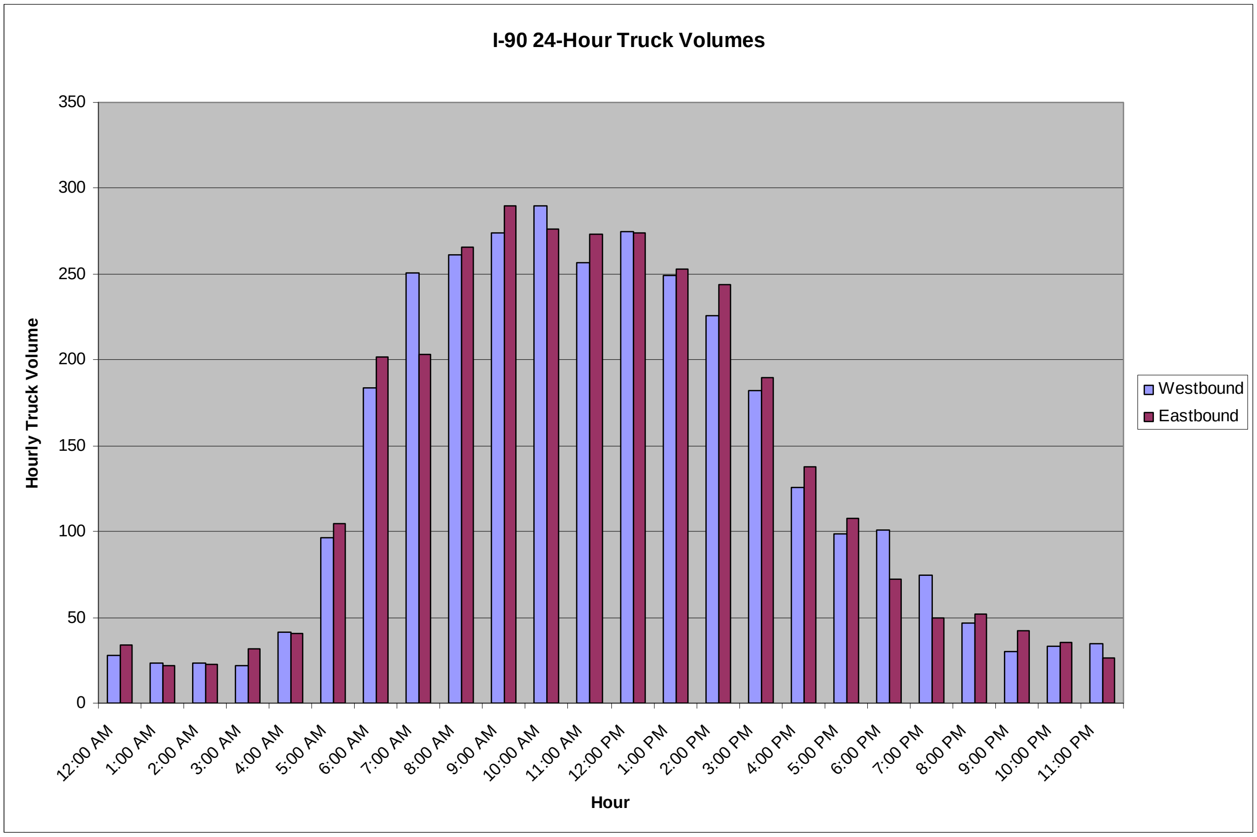
3.8.2.1 Regional Highways

In Segment A (see Exhibit 3-1), I-90 is a key east-west truck route within the study area, connecting local, interstate, and regional freight with the ports of Seattle and Tacoma and surrounding industrial areas. Following I-5, I-90 is the second most heavily used highway for truck movements in Washington (WSDOT, 2008). From 1993 to 2003, I-90 truck traffic grew by 72 percent (WSDOT, 2008).

Overall, about 6,300 trucks travel on I-90 across Lake Washington each day. This is about 4.5 percent of the approximately 140,000 vehicles that travel on the I-90 floating bridges every day. About half of the trucks are considered small-sized, which includes vehicles such as delivery vans and recreational vehicles. Approximately 12 percent of the total trucks crossing I-90 are large-sized tractor-trailer trucks. Trucks over 10,000 pounds (e.g., tractor-trailers) only travel on the outer I-90 mainline roadways because vehicles over 10,000 pounds are prohibited from using the reversible center lanes. Trucks under 10,000 pounds (e.g., delivery and recreational vehicles) are allowed to use the center roadway if they are either a high-occupancy vehicle or heading to/from Mercer Island. Therefore, there is only a small percentage of trucks in the reversible center roadway compared with the outer roadways in the study area. Throughout an average day, slightly over 100 small-sized trucks use the center roadway. This is about one percent of all the vehicles in this roadway.

About two-thirds of the trucks on I-90 travel during nonpeak hours, indicating many trucks avoid the more heavily congested times of the day. The highest amount of truck activity on I-90 crossing Lake Washington occurs during the period from late morning to mid-day. During the early afternoon, truck volumes dramatically decreases they avoid the afternoon peak period. Only about 3 percent of total traffic during the PM peak period is trucks. Exhibit 3-28 shows hourly truck volumes throughout the day.

During the AM peak period, about 40 percent of the trucks crossing Lake Washington on I-90 are heading to or from east of I-405, with many passing over Snoqualmie Pass. Overall, about 800 trucks travel on the I-90 mainline during the AM 2-hour peak period. This percentage of trucks continuing east on I-90 increases in the PM peak period to just over 50 percent, but, as described in the previous paragraph, the total number of trucks decreases dramatically in this period to about half, as approximately 400 trucks travel on I-90 during the PM peak period.



Source: Sound Transit, 2007

Note: I-90 total daily volume is approximately 140,000

EXHIBIT 3-28

I-90 Existing 24-Hour Truck Volumes

3.8.2.2 Arterials and Local Streets

In Seattle, most of the arterial streets within the study area (such as Rainier Avenue South, 4th Avenue South, and South Dearborn Street) are designated as Major Truck Streets, for which standards for design provide for higher volume truck travel. On Mercer Island, no roadways are identified as truck routes.

In Segments B and C, many of the arterial roadways with access to and from I-90 or I-405 are designated trucks routes, including Bellevue Way SE, 112th Avenue SE, SE 8th Street, NE 4th Street, and NE 8th Street. In addition, NE 12th Street is a truck route connecting Bellevue Way, 112th Avenue NE, and 116th Avenue NE, which are also designated as truck routes in Bellevue. Within Segment C, trucks mainly serve the commercial, office, and retail areas for delivery trips.

Within Segment D, Bel-Red Road is identified as a truck route. Other truck routes that access the commercial and industrial land uses along the Bel-Red corridor are 116th, 120th, 124th, and 148th Avenues NE. 148th Avenue NE, with access to SR 520, is also a designated truck route within Segment E. Also in Segment E, 148th Avenue NE and a small section of NE 51st Street are designated as truck routes in the city of Redmond. Near Downtown Redmond, West Lake Sammamish Parkway and SR 202 are designated truck routes that serve the commercial, retail, and office land uses.

3.8.2.3 Rail Freight

Within the study area, the only rail-line is the former BNSF Railway, which travels through Segments B, C, and D. There are no rail freight operations within Segments A and E. The Port of Seattle has acquired the former BNSF Railway right-of-way from Snohomish to north Renton, including a spur from Woodinville to Redmond. The Port of Seattle intends to secure the corridor for potential future freight rail use but is also interested in optimizing the use of this corridor for other transportation modes compatible with freight rail (Port of Seattle, 2008). The former BNSF Railway no longer is used for freight movements as the Wilburton Tunnel that crosses over southbound I-405 was recently removed, and therefore the rail corridor is no longer continuous.

3.8.3 Environmental Impacts

3.8.3.1 Impacts during Operation

Freight on Regional Highways

Future truck travel was analyzed along I-90 to understand future conditions with and without the project. This analysis provided 2-hour peak truck travel time data that are presented in Table 3-33.

As further described in this section, the East Link Project would have an overall beneficial impact on trucks traveling on I-90. As more people choose to use light rail, truck travel times during peak hours would be maintained or improve overall, and the ability for trucks to cross Lake Washington on I-90 would be maintained. Future traffic forecasts indicate that the average annual truck traffic growth by year 2030 on I-90 in the study area will be about 2 percent or less during the AM and PM peak periods. Growth in the peak periods between years 2020 and 2030, especially the PM peak period, is expected to minimize, as traffic congestion on I-90 will be much worse than it is today, and, therefore, a higher percentage of trucks are expected to cross Lake Washington during off-peak times. With more congestion in the future, there will be fewer uncongested off-peak hours available for truck travel in the no-build condition.

With either No Build Alternative (with Stages 1 and 2 of the I-90 Two-Way Transit and HOV Operations Project, or with Stages 1-3), afternoon and morning truck travel times in 2030 are expected to take 35 to 75 percent longer than at present due to increasing congestion. Overall, average (combined westbound and eastbound) truck travel time between I-405 and I-5 in the no-build condition would take approximately 24 minutes in the morning peak and 27 minutes in the afternoon peak.

With the East Link project, truck access to and from the I-90 westbound and eastbound outer roadways would be unchanged because none of the general-purpose ramps to and from I-90 would be modified with the project. Regarding truck travel times, the average truck travel time in the morning and afternoon peak periods would be 23 and 22 minutes, respectively, between I-405 and I-5, compared with 24 minutes in the morning peak and 27 minutes in the afternoon peak with either No Build Alternative (see Table 3-32). This equates to a comparable travel time in the morning peak and a 5-minute travel time savings in the afternoon peak. Most of the travel time improvement in the afternoon peak is in the westbound direction as a result of people shifting to ride light rail as their transportation mode, combined with the fact that truck access and circulation on the outer roadways would not be affected by East Link**.**

In addition to truck travel times, Table 3-32 also provides information on how many trucks would travel on I-90 during peak periods in 2030. Overall, the number of trucks traveling on I-90 in the morning and afternoon peak periods would be more with the project compared with the No Build Alternative when Stages 1 through 2 of the I-90 Two-Way Transit and HOV Operations Project are completed and similar when compared with the No Build Alternative when Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project are completed.

TABLE 3-33
2030 2-Hour Peak-Period I-90 Bridge Truck Volumes and Travel Times

Period	Direction	No Build Alternative[a]		No Build Alternative[b]		East Link	
		Number of Trucks[c]	Travel Time[d] (min)	Number of Trucks[c]	Travel Time[d] (min)	Number of Trucks[c]	Travel Time[d] (min)
AM Peak	Westbound	410	30	440	27	430	25
	Eastbound	480	18	570	21	620	22
AM Peak Total		**890**	**24**	**1,010**	**24**	**1,060**	**23**
PM Peak	Westbound	450	33	470	32	660	25
	Eastbound	340	21	570	22	370	20
PM Peak Total		**790**	**27**	**1040**	**27**	**1,020**	**22**

[a] With Stages 1 and 2 I-90 Two-Way Transit and HOV Operations Project.
[b] With Stages 1 through 3 of the I-90 Two-Way Transit and HOV Operations Project.
[c] Based on I-90 throughput data from the VISSIM analysis at the I-90 Lake Washington bridges.
[d] Travel times are between I-405 (Bellevue) and I-5 (Seattle).

More trucks would cross I-90 in the non-peak directions (eastbound in the morning and westbound in the afternoon) because congestion would improve with people riding light rail instead of driving. In the peak directions, a similar to less number of trucks would cross I-90 because congestion would remain similar with the project as the reversible center roadway would be closed to vehicles.

Currently, during non-peak periods auto congestion on I-90 is substantially reduced even though truck traffic is at much higher levels. Because congestion is less during these periods, the project, compared with the no-build condition, is not expected to have an impact on truck travel times during these periods. Thus, the bulk of the truck traffic would remain unaffected by the project.

The design options to potentially close the eastbound HOV direct-access off-ramp or westbound HOV direct-access on-ramp with Bellevue Way and design options for the eastbound HOV off-ramp at Mercer Island are not expected to cause impacts or circulation changes for trucks because these ramps are restricted to HOV and transit usage. Similarly, closing the Mercer Island ramps to and from the reversible center roadway is not expected to cause truck circulation impacts because similar access would be provided on the outer roadways.

Freight on Arterials and Local Streets

The alternatives in the East Link Project are not anticipated to negatively affect truck circulation or routes on the local street network. In some locations, local designated truck routes would cross or travel alongside of light rail at-grade profiles. At these locations, intersection conditions with East Link would be similar to those under the No Build Alternative. Some intersection operations may improve through mitigation for the East Link Project. Additionally, many of the at-grade alternatives that travel through intersections would be accommodated within the existing traffic signal operations. Therefore, disturbances caused by the light rail would be minimized, although slight delays could occur on the side streets when light rail travels through the intersection.

Rail Freight

Within Segment A, no rail freight impacts are expected. Within Segments B, C, and D, rail freight along the former BNSF Railway corridor is not anticipated to occur in the near-term future because of the recent I-405 expansion that removed a segment of rail line. The project, however, would not preclude future rail freight operations on the former BNSF Railway tracks. There are no rail freight operations within Segment E.

3.8.3.2 Impacts During Construction

This section discusses activities that could occur during construction and the associated impacts on freight. Construction impacts on trucks could include changes in travel time, truck routes, or business access.

Sound Transit would coordinate with WSDOT on incident management, construction staging, and traffic control permitting where the light rail construction might affect freight traffic. Sound Transit would also coordinate with WSDOT to disseminate construction closure information to the freight community.

Interstate 90

In Segment A, the I-90 Two-Way Transit and HOV Project would be completed before East Link is constructed on I-90 and Mercer Island. Therefore, truck travel times during the East Link construction period for the AM and PM peak periods would be similar to or less than the truck travel times with the No Build Alternative when only Stages 1 and 2 of the I-90 Two-Way Transit and HOV Project are built.

Similarly, compared to the No Build Alternative when Stages 1 through 3 of the I-90 Two-Way Transit and HOV Project are built, truck travel times during East Link construction would be similar or improved. Overall, a similar or increased number of trucks would cross Lake Washington during East Link construction compared with either No Build Alternative.

Most truck trips currently travel on I-90 during non-peak periods, when congestion is substantially reduced. Since congestion is less during these periods, project construction is not expected to have an impact on travel times for most truck traffic.The D2 Roadway would also be closed for light rail construction of the *Preferred Alternative A1*. This closure would not impact trucks as they are prohibited from using the D2 Roadway.

At the Bellevue Way interchange with I-90, the I-90 westbound mainline, HOV direct-access ramps, and ramps to and from I-90 to the east would experience short-term partial closures (likely during the nighttime) to construct the elevated structures for Alternatives B2A, B2E, B3, and B7 and *Preferred Alternative B2M*. The Bellevue Way Alternative (B1) would not require these closures because it is at-grade underneath the mainline roadway. These closures are not expected to affect trucks because alternative routes are available and truck traffic using these ramps is relatively low.

Other Regional Freeways

Elevated portions of the alternatives in Segment C over I-405 would likely result in multiple lane closures of I-405 at night, causing trucks to potentially detour and be delayed. Likewise, elevated portions of Alternatives E1 and E4 that would cross over SR 520 near the West Lake Sammamish Parkway interchange and the elevated portion of Alternative E1 that would cross SR 520 near the SR 202 interchange would close multiple lanes of SR 520 at night, causing trucks to potentially detour with added delay.

Arterials and Local Streets

Segment A

In Segment A, no truck impacts are expected on the arterial and local streets because light rail construction of the *Preferred Alternative A1* would be on the D2 Roadway and the I-90 reversible center roadway. Closing ramps to and from the I-90 reversible center roadway and constructing the Rainier and Mercer Island stations are not expected to affect trucks along arterials and local streets.

Segment B

Constructing all Segment B alternatives, except Alternative B7, would cause detours and lane closures on arterials and local streets, which could delay truck traffic on Bellevue Way and 112th Avenue SE. However, most of the businesses in South Bellevue are professional offices that do not rely heavily on trucks.

Segment C

Segment C at-grade (*Preferred Alternative C11A* and Alternatives C4A and C9A) and tunnel alternatives that require substantial cut-and-cover construction (*Preferred Alternative C9T* and Alternatives C1T and C2T) would have similar impacts on freight mobility and access on their construction routes. For these alternatives, short-term traffic detours and lane closures are expected. These might affect trucks and could require temporary alternate business access.

Constructing the Alternative C1T along Bellevue Way and NE 6th Street and Alternative C2T along Main Street, 106th Avenue NE, and NE 6th Street would require the largest amount of cut-and-cover tunnel construction. Converting 108th and 110th Avenues NE to one-way operations under Alternative C4A would require traffic detours and lane closures that might affect trucks and might temporarily alter business access.

Along elevated routes in Segment C, some impacts are anticipated as a result of lane closures and access restrictions needed for elevated structure construction. For Alternative C8E, impacts could occur along 110th Avenue NE because of lane closures.

For any of these alternatives, access to the businesses along streets with construction activities would be maintained to the extent possible either through existing or alternative access. Any access closures would be coordinated with the affected business.

Segment D

In Segment D, loss of parking, construction traffic, and lane closures could affect trucks along portions of NE 16th Street, 136th Place NE, NE 20th Street, 152nd Avenue NE, and NE 24th Street. Each alternative within Segment D would cause temporary detours and lane closures along some of these streets. Alternative D3 is expected to have the longest impact because it includes at-grade and retained-cut construction in the median of NE 20th Street. This construction could cause longer impacts on trucks than the other alternatives because other alternatives do not travel along NE 20th Street. *Preferred Alternative D2A* would have the second least impacts on trucks with impacts mainly along NE 16th Street and 136th Place NE. Alternative D5 would likely have the least impacts because most of it would be built adjacent to SR 520.

For the portions of the Segment D and E alternatives adjacent to SR 520, streets that currently provide access to properties would be rebuilt, as appropriate.

Segment E

In Segment E, the potential loss of lanes on Leary Way with Alternative E4 and 161st Avenue NE between Redmond Way and NE 85th Street with the Alternative E2 – Redmond Transit Center Design Option could have a slight impact on trucks. No substantial impacts are expected with the other Segment E alternatives during construction.

Maintenance Facilities

The impacts on trucks from constructing the maintenance facilities (potential detours and/or lane closures) are considered minimal because construction is expected to occur for about one year or less.

Rail Freight

Rail freight would not be affected in any segment during construction because the only rail line near East Link construction—the former BNSF Railway line in Segments B, C, and D—is closed.

3.8.4 Potential Mitigation

The East Link Project is not expected to require mitigation during operation to improve freight mobility and access because truck routes would be maintained and mobility would be improved with the project.

During East Link construction, adverse truck impacts would likely be associated with delays and restricted access for business deliveries on arterials and local streets near surface construction activities. The cut-and-cover tunnels and stations in Segment C would likely have the greatest impact on nearby businesses in terms of restricted access. To minimize these impacts, Sound Transit would work specifically with affected businesses throughout the construction period to maintain access as much as possible to each business.

During East Link construction associated with I-90, SR 520, or I-405, Sound Transit would coordinate with freight stakeholder groups by providing construction information to WSDOT for use in the state's freight notification system. Sound Transit would provide information in a format required by WSDOT and compensate WSDOT for any direct costs associated with use of the freight notification system for East Link construction.

3.9 Navigable Waterways

3.9.1 Affected Environment

Lake Washington is the largest navigable waterway in the study area. Navigation on Lake Washington is restricted to recreational users; commercial activity is prohibited except for some fishing by the Muckleshoot Indian Tribe in the tribe's "usual and accustomed" fishing area. The tribe conducts a fishing event in July in consultation with the Washington Department of Fish and Wildlife (WDFW).

Boaters can cross under I-90 at two locations on Lake Washington: under the east end of the I-90 bridges between Seattle and Mercer Island, and under the East Channel Bridge between Mercer Island and Bellevue.

Other water bodies located in the study area include smaller lakes, streams, and river bodies, including Mercer Slough, Mercer Slough East Creek, East Lake Bellevue, Sturtevant Creek, Kelsey Creek, Goff Creek, Sears Creek, Bear Creek, and the Sammamish River. Mercer Slough and the Sammamish River are navigable to nonmotorized watercraft; the other water bodies are not navigable.

3.9.2 Environmental Impacts

3.9.2.1 Operational Impacts

The operation of the East Link Project in Segment A would not affect navigation on Lake Washington.

Impacts on navigability in Segment B are not anticipated with *Preferred Alternative B2M* and Alternatives B1, B2A, B2E, B3, and B3 - 114th Extension Design Option because they are located outside the navigable waterways of the Mercer Slough Nature Park. The elevated profile of Alternative B7, adjacent to the I-90 overpass, would cross Mercer Slough East; however, recreational navigability on the Mercer Slough under I-90 would not be affected by this alternative.

The project alternatives in Segments D and E are not expected to impact navigability of water bodies crossed by these alternatives because most of these water bodies are not navigable. Alternatives crossing the Sammamish River would be elevated crossings, thus maintaining recreational navigability.

3.9.2.2 Construction Impacts

Some in-water work is anticipated to occur in Lake Washington along I-90, and some construction work could be conducted from a barge. Neither of these activities would affect navigability of the lake.

Over-water construction of Alternative B7 might result in short durations of restricted recreational boating inside Mercer Slough near and under the Alternative B7 crossing.

Similarly, constructing the *Preferred Alternative E2* and Alternatives E1 and E4 might restrict nonmotorized boating on the Sammamish River at light rail crossings for short periods.

3.9.3 Potential Mitigation

During East Link operation, no mitigation of impacts on navigable waterways would be required.

During construction, Sound Transit would minimize impacts on the navigability of the Mercer Slough (Alternative B7) and the Sammamish River (all Segment E alternatives) waterway crossings by minimizing work from within the waterways.

If any barging of construction equipment or materials is required on Lake Washington in July, Sound Transit would consult with the Muckleshoot Indian Tribe to avoid conflict with their tribal fishing event.

Chapter 4

Affected Environment and Environmental Consequences

This chapter reviews the affected environment and environmental consequences for each resource analyzed. Each subsection describes the pertinent study area, the applicable regulations followed, and the effects of the preferred alternatives and other alternatives considered, including the No Build Alternative. Where impacts could not be avoided and minimized to avoid adverse effects, mitigation measures are proposed.

4.1 Acquisitions, Displacements, and Relocations

4.1.1 Introduction to Resources and Regulatory Requirements

Building and operating the East Link light rail system would require acquiring public and private property for right-of-way and other facilities, as well as displacing and relocating some residential, commercial, and public uses. This section summarizes likely property acquisitions, including property needed for elevated guideway easements, based on current conceptual designs and their impacts in each segment, while focusing on major differences among alternatives. This list of acquisitions is representative and should not be considered the final determination regarding property acquisition; the list could be updated as the project design is refined. Furthermore, the estimates described below reflect the existing conditions at the time the analysis was conducted. Because properties that are currently underdeveloped or vacant could be developed between completion of this Final EIS and the time of construction, the number and/or type of displacements could vary between what is disclosed in the Final EIS and what would actually be required.

There are two types of property acquisition discussed in this section:

- **Partial acquisition**, which would acquire part of a parcel and generally would not displace the existing use. In a few instances some of the businesses or residential units on a parcel would be displaced.
- **Full acquisition**, which would acquire the full parcel and displace the current use; full acquisitions include parcels that might not be fully needed for the project but would be affected to the extent that existing uses would be substantially impaired (e.g., loss of parking or access).

Within Segment C, many of the full acquisitions would be for staging areas and would only be needed during construction. Following construction, many of these properties would be available for redevelopment. Because of the length of time needed for civil construction—generally between 2 and 5 years—all displacements presented would be permanently relocated, and future redevelopment of staging areas would attract new businesses and residents.

In addition to the potential property acquisitions described in this section, the East Link Project would require subterranean easements, temporary construction easements, and the use of public rights-of-way owned by the Washington State Department of Transportation (WSDOT), the City of Bellevue, the City of Redmond, the Port of Seattle, and possibly the Cities of Seattle and Mercer Island and King County (Table 4.1-1). The area of these easements is not included in the data presented here. Other impacts associated with acquisitions and displacements are discussed in Section 4.2, Land Use; Section 4.3, Economics; and Section 4.4, Social Impacts, Community Facilities, and Neighborhoods.

TABLE 4.1-1
Potential Permanent Easements for Public Lands or Facilities

Type of Facility	Agency and/or Facility Owner	Facility Name	Segments
State roads	WSDOT	SR 520, SR 202, and SR 908	D, E
Interstates	WSDOT	I-90 and I-405	A, B,C
Local roads and property	Cities of Bellevue, Redmond, and Mercer Island; King County	Multiple	B, C, D, E
State waters	Washington Department of Natural Resources	Lake Washington, Sammamish River and Mercer Slough	A, B, E
Railroad corridor	Port of Seattle	Former BNSF Railway	B, C, D, E

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Code of Federal Regulations [CFR] Title 49, Part 24), as amended, is a federal requirement, and therefore, compliance is assumed as part of the project. The act and its amendments provide guidance on how federal agencies, or agencies receiving federal financial assistance for a project, will compensate for impacts on property owners or tenants who need to relocate if they are displaced by the project.

Sound Transit also has an adopted *Real Property Acquisition and Relocation Policy, Procedures, and Guidelines* to guide its compliance with Chapter 8.26 Revised Code of Washington (RCW) and Chapter 468-100 Washington Administration Code (WAC). Property acquisition will meet these laws and policies so that property owners are treated uniformly and equitably.

4.1.2 Affected Environment

The study area for acquisitions, displacements, and relocations includes parts of the Cities of Seattle, Mercer Island, Bellevue, and Redmond and King County. These jurisdictions are heavily developed with residential, commercial, industrial, and public properties along the proposed light rail corridor. Current and projected land uses along each alternative are discussed in Section 4.2, Land Use.

4.1.3 Environmental Impacts

Sound Transit analyzed the proposed right-of-way boundaries and parcel data from King County Department of Assessments and the City of Bellevue to identify properties that would be affected by each alternative and the area of each parcel that would be required. The tables and maps in Appendix G2 identify each potentially affected parcel by alternative; these maps show the right-of-way needed for the project and identify the parcels that would be affected, but they do not differentiate between partial and full acquisitions.

Sound Transit evaluated the effects on each parcel to determine whether the parcel would be fully or partially acquired. Sound Transit verified the current land use, including the number of businesses or residences on affected parcels, using 2010 King County Assessor data and field verification. The number of acquisitions and displacements for each segment within an alternative, as well as for each connector in Segments C and D, was then summarized in Table 4.1-2 and in Appendix G2.

4.1.3.1 No Build Alternative

Under the No Build Alternative, no acquisitions would be required, and no displacements or relocations would occur.

4.1.3.2 Impacts During Operation

Besides property acquisition, the East Link Project would require a number of permanent easements in public lands, waterways, and roadways. Table 4.1-1 lists the easements required by the alternatives, although actual easement areas required would vary by alternative. Sound Transit is in the process of acquiring 1.1 miles of the former BNSF Railway corridor from the Port of Seattle in Segments C and D, as well as an easement in other sections of the corridor potentially used by East Link.

Table 4.1-2 summarizes the total acres of property that would be required for each alternative (and alternative-connector combination), maintenance facility, and storage tracks, compared with the number of affected parcels, including partial and full property acquisitions. This area does not include public right-of-way that would be used as an easement. Property acquisitions related to stations are included in the total for the alternative but are also discussed separately in the following discussion of acquisitions in each segment. Table 4.1-3 summarizes the number of parcels potentially affected, which includes full and partial property acquisitions. In addition, these acquisitions are broken down by the type of land use affected by each alternative (and connector) in Segments B through E and the maintenance facility alternatives. The property acquisition for each alternative would include the light rail route, station (including park-and-ride lots), traction power substations (TPSS), and other facilities as needed for the build out of the alternative. The number of anticipated business and residential unit displacements are provided and might result from either full or partial acquisitions. These acquisitions and displacements are discussed and compared within each segment. It is important to note that many, but not all, of the partial acquisitions would be considered “sliver” acquisitions because they are small in size and would not affect the use of the property; however, because each “sliver” acquisition is counted among the total acquisitions, it could wrongly be inferred, due to a higher number of these “sliver” acquisitions, that one alternative would result in greater impacts than others would.

TABLE 4.1-2
Summary of Property Acquisition Impacts by Segment [a]

Segment	Alternative and Connector		Area to be Acquired by Project (acres) [a]	Total Number of Parcels Affected
Segment A	*Preferred Interstate 90 Alternative (A1)*		0	0
Segment B	*Preferred 112th SE Modified Alternative (B2M)*	To *Preferred Alternative C11A*	16.8	16
		To *Preferred Alternative C9T*	17	16
	Bellevue Way Alternative (B1)		20.2	92

		Alternative D5	31.5	23
	BNSF Maintenance Facility (MF2)	*Preferred Alternative D2A* and Alternatives D2E and D3	24.9	10
		Alternative D5	22.9	9
	SR 520 Maintenance Facility (MF3)	*Preferred Alternative D2A*	19.2	14
		Alternative D2E	19.2	14
		Alternative D3	17.2	15
		Alternative D5	15.0	9
	SE Redmond Maintenance Facility (MF5)	Alternative E1	21.1	17
		Preferred Alternative E2	15.1	12
		Alternative E4	14.6	9

Note: This table does not include public rights-of-way (city or WSDOT) or former BNSF Railway corridor rights-of-way. Refer to the design drawings in Appendix G1 for public rights-of-way identified for the project.

[a] Includes area that would be acquired in full and partial property acquisitions.

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts with either *Preferred Alternative C9T* or *B2M.*

[c] Impacts with D2A – 120th Station Design Option would be the same as those with *Preferred Alternative D2A*.

Note: This table does not include public rights-of-way (city or WSDOT) or former BNSF Railway rights-of-way. Refer to the design drawings in Appendix G1 for public rights-of-way identified for the project.

[a] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M.*

[b] Impacts for D2A – 120th Station Design Option would be the same as they are for *Preferred Alternative D2A*.

The amount of land area converted to public right-of-way (Table 4.1-2) and the number of displacements caused by property acquisitions (Table 4.1-3) are a better representation of the impact than the number of properties affected.

Segment A

Sound Transit identified no right-of-way acquisition needed for *Preferred Interstate 90 Alternative (A1)* in this segment outside the existing public roadway, or highway rights-of-way.

Segment B

Sixteen properties would be affected by *Preferred 112th SE Modified Alternative (B2M)*, with either connection to *Preferred 108th NE At-Grade Alternative (C11A)* or *Preferred 110th NE Tunnel Alternative (C9T)*. Of these 16 properties, only 1 property, the South Bellevue Park-and-Ride, would be fully acquired for the South Bellevue Station and Park-and-Ride.

Of the Segment B alternatives, *Preferred Alternative B2M* and 112th SE Elevated Alternative (B2E) would have the fewest displacements. Neither would displace businesses, and only one residence would be displaced with these alternatives.

The Bellevue Way Alternative (B1) would have the greatest number of acquisitions and displacements—72 partial and 20 full property acquisitions—thereby displacing and relocating 2 businesses and 12 residences. The BNSF Alternative (B7) would affect the fewest number of overall parcels besides *Preferred Alternative B2M* (17) but would fully acquire eight parcels, thereby displacing six businesses. Four of these full acquisitions and three business displacements would be for the 118th Station. The B3 - 114th Extension Design Option would impact four more properties than Alternative B3. This design option would impact properties just north of the Mercer Slough.

Similar to *Preferred Alternative B2M*, most of the Segment B alternatives that run along Bellevue Way SE (Alternatives B1, B2A, B3, and B3 -114th Design Option) would displace the residence at the Mercer Slough Blueberry Farm.

Segment B alternatives serving the South Bellevue Station, similar to *Preferred Alternative B2M*, would fully acquire the South Bellevue Park-and-Ride property. The SE 8th Station would partially acquire two commercial properties under Alternative B2A, but no businesses would be displaced. All Segment B alternatives would acquire a small portion of Mercer Slough Nature Park.

Segment C

Most land for property acquisitions in Segment C would be for construction staging areas. Due to the highly developed nature of the land in this segment, specific staging areas have been identified for each alternative. These staging areas are shown in Section 2.4 of Chapter 2 and in Appendix G2. More detail on the needs of these areas is provided in Section 4.1.3.3, Construction Impacts.

Preferred Alternative C11A connecting to *Preferred Alternative B2M* would partially acquire 30 properties and fully acquire 28 properties. Seven residential properties would be fully acquired, thereby displacing 46 residential units (5 single-family and 41 multifamily units). The multifamily residential displacements include two condominium complexes along 112th Avenue SE. *Preferred Alternative C11A* and its connection to *Preferred Alternative B2M* would displace 39 businesses; most of these business displacements are offices along Main Street and commercial businesses along 108th and 116th Avenues NE. *Preferred Alternative C11A* would require a partial acquisition of Surrey Downs Park, parallel to 112th Avenue SE, which would not affect any uses of the park. Construction of the Hospital Station would require acquisition to the east of the former BNSF Railway corridor. Widening the corridor to the west would likely require additional larger and more costly property acquisitions on the west side of the former BNSF Railway corridor (such as the Whole Foods site) and to other commercial properties on the south side of NE 8th. This widening would also be required for any alternative that includes the Hospital Station.

For the *Preferred Alternative C11A* connection to Alternatives B3, B3 - 114th Extension Design Option or B7, one additional business displacement and one residential displacement would occur; the business displacement would be a hotel on 112th Avenue SE for the East Main Station.

Preferred Alternative C9T connecting to *Preferred Alternative B2M* would displace 17 businesses and 46 residences. These residential displacements would include five single-family residences and two condominium complexes. *Preferred Alternative C9T* would acquire 0.5 acre of Surrey Downs Park for relocation of SE 4th Street, which would impact the eastern portion of the King County District Court building. This portion of the building does not include the core functions of the public facility. If the courthouse is not relocated before project construction, this portion of the building would be removed and the remainder of the building would be restored and the core functions of the courthouse would remain. This public facility, however, might be relocated before East Link construction. This alternative would also partially acquire the NE 2nd Pocket Parks for the south entrance to the Bellevue Transit Center Station, as described in Section 4.17, Parkland and Open Space. If the optional station at Main Street for *Preferred Alternative C9T* were selected, it would not require any additional parcel acquisitions.

For connections to Alternatives B3, B3 - 114th Extension Design Option and B7, a hotel on 112th Avenue SE would be displaced for the East Main Station, similar to *Preferred Alternative C11A*.

For all Segment C alternatives, except the Bellevue Way Tunnel Alternative (C1T), most business displacements and impacts would be related to construction staging areas, which would be a temporary use of this land. Areas of these properties not needed for right-of-way would be available for redevelopment following construction. Park areas used for staging would be restored as described in Section 4.17, Parkland and Open Space.

Alternative C1T would have a high number of residential relocations (91 residential units) related to widening Bellevue Way SE where the light rail would be at-grade and descend to below grade. The 21 business displacements for this alternative would mostly involve smaller buildings or strip malls that contain three or fewer businesses, and would all be for staging areas. The residential displacements would include one 60-unit apartment complex, one 24-unit apartment complex, and one 7-unit apartment building that is part of a larger complex. Part of one public property, which is adjacent to Bellevue City Hall and owned by King County, is currently vacant and would be acquired. This same public property would also be acquired partially for *Preferred Alternatives C11A* and *C9T* and 110th NE At-Grade Alternative (C9A) and fully for 106th NE Tunnel (C2T), 112th NE Elevated (C7E), and 114th NE Elevated (C14E) Alternatives.

Alternative C2T would have the fewest number of business displacements—between 14 and 21—depending on the connection to Segment B. Business displacements for the 108th NE Tunnel (C3T), Couplet (C4A), C7E, 110th NE Elevated (C8E), 110th NE At-Grade (C9A) and 114th Elevated (C14E) Alternatives would be between 15 and 36 businesses. Under these alternatives, most business displacements would be small businesses in buildings that contain one or two businesses. However, Alternatives C7E and C8E would displace a business park with 22 businesses.

Four alternatives could have no residential displacements: Alternatives C2T (when connecting to Alternative B2A), C7E, C9A (when connecting to Alternative B3, B3 – 114th Design Option or B7), and C14E. Residential displacements would range from 1 and 19 units for the remaining connectors with Alternative C2T, and for Alternatives C3T, C4A, C8E, and C9A.

Alternatives C2T and C3T would require partial acquisition of Surrey Downs Park and displace the King County District Court building when connecting to Alternative B2A. This facility, however, might be relocated by King County prior to this project. Alternatives C4A and C7E would also acquire small portions of Surrey Downs Park but would not affect the Court Building. Alternatives C3T, C4A, and C8E would remove portions of McCormick Park, but this area would be replaced in kind following the project so that there would be no loss of parkland; as a result, parkland would actually increase for all three alternatives. Further discussion of impacts on these parks is provided in Section 4.17, Parkland and Open Space.

All Segment C alternatives except C1T and C14E would acquire and displace one business for the East Main Station if connected with Alternative B3, B3 - 114th Extension Design Option, or B7.

Segment D

All Segment D alternatives would connect to *Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C9A, and C14E via the former BNSF Railway corridor after these alternatives cross I-405 south of NE 8th Street. This connection would require fewer acquisitions for all Segment D alternatives than connecting from NE 12th Street. The remaining Segment C alternatives would cross I-405 at NE 12th Street and would need to cross several commercial properties on the east side of 116th Avenue NE to access the former BNSF Railway corridor, thereby increasing the number of acquisitions for Segment D alternatives connecting to these Segment C alternatives. Segment D alternatives would not displace any residential properties.

With *Preferred NE 16th At-Grade Alternative (D2A)*, eight properties would be fully acquired. *Preferred Alternative D2A* would also displace 34 businesses, most of which are industrial and commercial businesses along NE 15th Street, 130th Avenue NE, and 136th Place NE. The 120th Station would displace 1 business, and 14 businesses would be displaced by the Overlake Village Station.

The storage track, located along the former BNSF Railway corridor north of NE 12th Street would partially acquire only four properties. No business or residences would be displaced by the storage track. For D2A - NE 24th Design Option, 28 businesses along the west side of 152nd Avenue NE would be displaced by the Overlake Village Station.

The NE 20th Alternative (D3) would have the greatest impact, with up to 107 parcels affected and up to 74 businesses displaced when connecting to the Segment C alternatives that cross NE 12th Street. The SR 520 Alternative (D5) would affect the fewest parcels (between 39 and 44) and would displace 79 businesses with either connection to Segment C. The station at 130th Avenue NE would displace eight businesses under Alternative D2E and seven businesses under Alternative D3. The Overlake Village Station option north of NE 24th Street would displace ten businesses under Alternative D5, and six businesses would be displaced by the Overlake Village Station with Alternative D2E.

Segment E

With *Preferred Marymoor Alternative (E2)*, 36 properties would be potentially affected: 10 full acquisitions and 26 partial acquisitions. Two single-family properties and seven commercial properties would be fully acquired. *Preferred Alternative E2* would displace eight business and two residences. With *Preferred Alternative E2*, the SE Redmond Station would displace three businesses. This alternative would also partially acquire an area of Marymoor Park along the south side of SR 520.

The E2 - Redmond Transit Center Design Option would impact the same property as *Preferred Alternative E2*, in addition to properties along 161st Avenue NE. Widening 161st Avenue NE for the Redmond Transit Center Station would displace ten businesses. Property along the southwest edge of a city park along 161st Avenue NE would be acquired for the portion of this design option that runs along 161st Avenue NE.Although the Redmond Way Alternative (E1) would affect a greater number of parcels than the Leary Way Alternative (E4) (43 and 35, respectively), both would displace two single-family residences. Alternative E1 would displace 7 businesses whereas Alternative E4 would displace 7 businesses. Most businesses displaced by this segment would be industrial properties or auto-related businesses that require larger properties. No public or institutional properties would be displaced by Alternative E4.

Alternative E1 would partially acquire Luke McRedmond Park, and all three Segment E alternatives would acquire a small portion of the Sammamish River Trail right-of-way. Public parkland acquired would be mitigated through replacement, financial compensation, or enhancement. The Redmond Town Center Station would not require any displacements.

The City of Redmond has plans for locating a trail within the former BNSF Railway corridor in Downtown Redmond as well as accommodating local and regional infrastructure projects, including Sound Transit’s light rail. Together, these uses have the potential to reduce the amount of space available for light rail under any Segment E alternative. This constraint might require that light rail be shifted to accommodate a stormwater pipe and trail, which in turn might require the partial acquisition of property to accommodate all proposed facilities.

Maintenance Facilities

Developing the maintenance facilities would not displace and residential properties. The 116th Maintenance Facility (MF1) and the SR 520 Maintenance Facility (MF3) could displace between 56 and 82 businesses, most of which are small offices in business parks. A Bellevue Fire Department training facility would be displaced by MF1. The BNSF Maintenance Facility (MF2) would have the fewest displacements overall, with only five or six businesses displaced, depending on to which Segment D alternative it connects. The SE Redmond Maintenance Facility (MF5) would displace between 16 and 38 businesses, depending on to which Segment E alternative it connects. Some public road right-of-way would be required as well for all maintenance facilities. MF5 would also acquire a small portion of the public right-of-way of the East Lake Sammamish Trail. Further discussion of impacts on the trail is located in Section 4.17, Parklands and Open Space.

4.1.3.3 Impacts During Construction

Property impacts during constructions would consist of staging area acquisition and temporary construction easements. Staging areas would be required in all segments, although specific locations for these are highlighted in Segment C, because the land is more heavily developed and the land would be used for the range a construction activities, including equipment storage, work coordination, and contractor offices. In the remaining segments, staging areas would generally be accommodated within areas permanently needed for right-of-way; therefore, additional property acquisition for staging areas is not expected. The contractor might lease or make arrangements for additional staging areas if needed. These are preliminary and might be refined during final design.

Temporary construction easements would be needed along the project alternatives in each segment and possibly the maintenance facilities to allow for project construction. Construction easements are temporary uses of property during construction and would be required in numerous locations along the route. In undeveloped land areas, easements would be necessary to maneuver equipment and materials during construction. Where the project follows an existing transportation corridor, construction activities might require narrow temporary easements from adjacent properties. Following construction, easements would be returned to preconstruction condition.

Major temporary construction easements are described below for each segment. Other smaller temporary easements would be needed throughout the project corridor but have not been identified at this time. The approximate size and location of major easements have been identified in Segments B and E. Refer to Section 2.4.2 for a discussion of construction easements, and refer to the tables and maps in Appendix G2 for the potentially affected properties which have been identified for the project.

Segment A

With *Preferred Alternative A1,* substantial work in Segment A would occur within the I-90 right-of-way, thereby requiring and no additional staging areas. Work might occur in Lake Washington during construction of the East Link Project on the I-90 bridge. Smaller temporary construction easements might be needed, particularly near stations and freeway ramp construction, and would be identified during final design.

Temporary construction easement

A temporary construction easement is the temporary use of a property during construction allowed through an easement from the property owner. Following construction, the easement is terminated, and the property is restored to its previous condition.

Segment B

Construction easements would be needed along the corridor on the west side and the east side of the route with *Preferred Alternative B2M*. While most staging could occur on the South Bellevue Park-and-Ride site, some additional easement would be needed nearby.

A temporary construction easement along the east side of Bellevue Way SE in Mercer Slough might be needed for all other Segment B alternatives except Alternative B7. Alternative B3 would also require a temporary construction easement on the north side of SE 8th Street and east of 112th Avenue SE. A temporary construction easement along the north side of I-90 in Mercer Slough would likely be needed for Alternative B7. These easements would be required to construct the guideway or for road reconstruction for portions of the alternatives. The Mercer Slough Blueberry Farm and the Eastside Heritage Center, located at the Winters House, would be temporarily relocated during construction, as discussed in Section 4.3, Economics, and Section 4.17, Parklands and Open Space.

Segment C

The staging area property acquisition identified in Segment C is generally located either adjacent to proposed stations, around tunnel portals, or where the project occurs outside of public right-of-way. These acquisitions are included in the total acquisitions listed in Table 4.1-3 and are not additional acquisitions.

With *Preferred Alternative C11A*, staging areas would be needed around the Bellevue Transit Center Station, on the west side of I-405 and south of and east of the Hospital Station. Staging would also occur on property to be acquired for project right-of-way along 112th Avenue SE and Main Street.

With *Preferred Alternative C9T*, staging areas would be needed around the Bellevue Transit Center Station and south of and east of the Hospital Station. Staging would also occur on property to be acquired for project right-of-way along 112th Avenue SE and Main Street.

With the other Segment C Alternatives, staging areas in Downtown Bellevue would typically acquire the full property and displace the existing use during the construction period. Staging areas proposed in Surrey Downs and McCormick Parks would be restored to park use. In most cases, parcels not needed for project operation would be available for redevelopment following construction, such as properties around the Bellevue Transit Center and Old Bellevue Stations.

The extent of redevelopment that could be accommodated at staging areas at or around the intersection of Main Street and 112th Avenue SE and the Hospital/Ashwood Station has not yet been determined.

Segment D

With *Preferred Alternative D2A*, temporary construction easements would be needed along the project corridor on each side of the route. This area would be widened or reduced in selected areas to avoid existing buildings or ecologically sensitive areas. With the other Segment D Alternatives, no additional construction areas have been identified.

Segment E

Temporary construction easements would be needed along the project corridor on each side of the *Preferred Alternative E2* route. This area would be widened or reduced in selected areas to avoid existing buildings or ecologically sensitive areas. A temporary construction easement on the south side of SR 520 in Marymoor Park would likely be needed for *Preferred Alternative E2*, in addition to easements around SR 520 and SR 202 discussed below.

All Segment E alternatives would require temporary easements on the west side of the SR 202 and SR 520 interchange within the Bear Creek riparian greenbelt. These areas would also be needed for constructing the guideway or for road reconstruction for portions of the alternatives.

Maintenance Facilities

All work for the selected Maintenance Facility is expected to occur within the acquired right-of-way and no additional easements or acquisition for staging areas is expected.

4.1.4 Eastside Relocation Opportunities

To measure relocation opportunities, Sound Transit researched available residential and commercial real estate in the project vicinity. Although property availability will change over time, this study indicates that there are numerous opportunities for residents and businesses to relocate within the project vicinity, which would minimize difficulties in adjusting to relocation. Table 4.1-4 summarizes the availability of different types of commercial property on the Eastside, generally defined as including Bothell/ Kenmore, Redmond, Kirkland, Bellevue, Issaquah, and Woodinville.

Relocation sites for multifamily residences and small businesses are expected to be readily available in the project vicinity due to a number of newly constructed mixed-use developments.

TABLE 4.1-4
Commercial Property Availability for Relocation on the Eastside

Commercial Property Type	Vacancy Rate (Q4, 2010)
Office [a]	15 percent
Retail [b]	8.7 percent
Industrial [c]	6.8 percent

[a] Colliers International, 2010.
[b] GVA Kidder Matthews, 2010.
[c] Colliers International, 2010.
Q4 - fourth quarter

Currently, over 3,000 apartment and/or condominium units are under construction, permitted, or planned to start construction within the next year on the Eastside (Cities of Bellevue and Redmond, 2010). Within mixed-use developments in Bellevue and Redmond, over 250,000 square feet of retail space is under construction, most of which is located in Redmond. According the Northwest Multiple Listing Service (2011), almost 600 condominiums were for sale in Bellevue and Redmond.

Relocation sites for single-family residences are also expected to be readily available in the same general area, but not necessarily in the same neighborhood. According the Northwest Multiple Listing Service, over 1,000 single-family residences were for sale in Bellevue and Redmond in March 2011. The number of single-family residences to be acquired in each segment is relatively small in proportion to the entire housing stock for the area; therefore, adequate relocations sites are expected to be available.

Relocation sites for industrial-oriented properties might be more difficult to find in the project vicinity because these land uses are being redeveloped for other purposes in some areas of Bellevue and Redmond, especially in Segment D (commonly referred to as the Bel-Red corridor). Under the preferred alternative for the City of Bellevue's Bel-Red Corridor Plan, there will be a loss of approximate 2.49 million square feet of industrial space, and an increase of 4 million square feet of office space and 500,000 square feet of retail space. In addition, 5,000 new housing units will be added to this area. For more information on this planned redevelopment, see Section 4.2, Land Use. According to current market analyses, most of the Eastside is experiencing an areawide increase in vacancies; however, the area's highest vacancies are located in Redmond (Colliers International, 2010). Relocation assistance would mitigate the displacements, but relocation could still represent an inconvenience or hardship to some property owners and tenants.

4.1.5 Sound Transit Acquisition and Relocation Policy Summary

Sound Transit would contact property owners whose property would be directly affected to answer questions and provide additional information about relocation assistance services, payments, and reimbursement eligibility. Sound Transit's relocation assistance and advisory services would include, but not be limited to, measures, facilities, or services that might be necessary or appropriate to determine the relocation needs and preferences of each household, business, and nonprofit organization to be displaced. Sound Transit would provide current information on the availability, purchase prices, and rental costs of comparable replacement dwellings.

Sound Transit is committed to working closely and proactively with residents and businesses to help them plan ahead for relocation, assist them in finding new homes or sites, and help solve problems as they might occur. While the ultimate choice of relocation site would be up to the affected resident or business, Sound Transit would help with detailed investigation of possible locations. For those who wish to remain in their neighborhood, Sound Transit would assist in finding a new location close to their current site. Interpreters have been and will continue to be used to assist those who do not feel comfortable speaking English so they can understand their choices and options.

Owners are not required to surrender possession of property until they have been paid the agreed purchase price or until an amount equal to Sound Transit's established estimate of just compensation has been deposited with the court. Owners and tenants would not be required to move their businesses without first being given at least 90 days written notice by Sound Transit.

Regarding needed improvements, it is generally recommended that property owners proceed with planned improvements to their properties or facilities as they deem necessary.

Property owners whose entire or partial property would be acquired by Sound Transit would receive just compensations for their land and improvements. Just compensation is an amount paid to a property owner for property acquired for public purposes that is not less than the fair market value of the property acquired, including damages or benefits to the remaining property. Compensation would include any measurable loss in value to the remaining property as a result of a partial acquisition. Permanent parking lots from partial acquisition would be mitigated by compensating the property owner or by providing replacement parking.

Sound Transit would pay for normal expenses of sale, including escrow fees, title insurance, prepayment penalties, mortgage release fees, recording fees, and typical costs incurred incident to conveying title. The sale, however, would be exempt from the real estate excise tax and would involve no real estate commissions. Funds remaining at the end of sale closing would be released to the seller.

Other benefits and compensation might include payment of residential moving expenses and replacement housing payments, nonresidential moving expenses, and reestablishment expenses. Sound Transit's Business and Residential Acquisition and Relocation handbooks outline compensation and acquisition procedures in detail.

The application of regulations and statutes to individual cases will be by the letter and intent of the law. Special circumstances can be recognized, and proactive help to solve problems is available. The timing and magnitude of purchase payments can be adjusted to fit circumstances and fundamental concepts of fairness.

4.1.6 Potential Mitigation Measures

As part of the project, Sound Transit would compensate affected property owners according to the provisions specified in Sound Transit's adopted *Real Estate Property Acquisition and Relocation Policy, Procedures, and Guidelines* (Resolution #R98-20-1) as summarized above. Sound Transit would comply with provisions of the federal Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Code of Federal Regulations [CFR] Title 49, Part 24), as amended (49 CFR, Part 24), and the State of Washington's relocation and property acquisition regulations (WAC 468-100 and RCW 8.26). Benefits would vary depending on the level of impact, available relocation options, and other factors. Because of these compliance actions, no additional mitigation would be necessary.

4.2 Land Use

4.2.1 Introduction to Resources and Regulatory Requirements

This section provides information on the existing land uses and current zoning (future allowable land uses), describes changes in land use that would occur as a result of the East Link Project, and evaluates the consistency of the project with local and regional planning policies.

Changes in transportation systems can influence changes in nearby land uses. The project can directly affect land use through property acquisition required for the project. Conversely, the project can be one factor in considering high-density development patterns. Regional plans identify the need to connect the urban centers within the study area with high-capacity transit as a method of efficient use of land, offering a sustainable alternative to increasing congestion problems.

What is transit-oriented development?

Transit-oriented development is a pattern of dense, diverse, pedestrian-friendly land uses located near transit nodes. Under the right conditions, this translates into higher transit patronage (Transit Cooperative Research Program, 2004).

Light rail can act as a catalyst for development and/or redevelopment in those station locations where jurisdictions have identified the desire for a greater density and mixture of land uses. In those areas where no land use changes are desired, the local jurisdictions control land use regulations and only the jurisdictions have the ability to make changes to directly influence land uses. In those areas where the jurisdictions decide to influence land use changes, light rail can indirectly influence development patterns and decisions toward a pedestrian-friendly environment around stations and support of transit ridership. This is because the stations increase transit accessibility and mobility and can draw large numbers of pedestrians to the vicinity. Under circumstances of available redevelopable land, proper market conditions, and appropriate adopted land use policies, transit-oriented development can be an indirect result of a light rail project, consisting of primarily higher-density, mixed-use development. Therefore, the land use study area for this Final EIS consists of the areas immediately adjacent to the route and the area within a 0.5-mile radius around the stations. The areas within 0.5 mile of the stations have the greatest probability of being affected, both directly and indirectly.

Appendix F4.2, Land Use Plans and Policies, lists plans and policies pertaining to the study area. For this evaluation, the project's land use compatibility and conformance with existing land use policies and plans was measured and compared to the following plans:

- Washington State Growth Management Act (GMA) (adopted 1990, as amended)
- *King County Comprehensive Plan* (adopted 2008, amended 2010) (King County, 2008)
- Puget Sound Regional Council (PSRC) *VISION 2040* (PSRC, 2008)
- PSRC *Transportation 2040* (adopted 2010) (PSRC, 2010a)
- *Sound Transit Regional Transit Long-Range Plan* (adopted July 2005)
- *Sound Transit 2, The Regional Transit System Plan for Central Puget Sound* (adopted May 2007)
- *Seattle's Comprehensive Plan: Toward a Sustainable Seattle*. (adopted 1994, amended 2008)
- Neighborhood plans for Chinatown/International District, Central Area, and North Rainier Valley (City of Seattle, 2004)
- Shoreline Master Programs for the Cities of Seattle, Mercer Island, Bellevue, and Redmond, and King County (Amended every 7 years)
- *Comprehensive Plan of the City of Mercer Island* (adopted 1994, amended 2004) (City of Mercer Island, 2005)
- *Design Principles for Mercer Island Town Center Light Rail* (City of Mercer Island, 2008)
- *City of Bellevue Comprehensive Plan* (Adopted 1993, amended 2010) (City of Bellevue, 2006)
- *City of Bellevue Sub-Area Plans and Transportation Facility Plans* (adopted 1993, amended 2010)
- *City of Bellevue Best Practices for Light Rail* (City of Bellevue, 2008)
- *Eastside Transportation Program* (City of Bellevue, 2008)
- *City of Redmond Comprehensive Plan* (adopted 1995, amended 2004/2007) (City of Redmond, 2007)
- *Overlake Hospital Medical Center Master Plan* (adopted 2000, amended 2005)

4.2.2 Affected Environment

The East Link Project is located within King County, and the alternatives travel through and would have stations located within four urbanized cities (Seattle, Mercer Island, Bellevue, and Redmond). Existing land uses in these jurisdictions include a mixture of single-family and multifamily residential, commercial retail and services, office uses, institutional uses, and light industrial uses. There are also a number of recreational and public open spaces located adjacent to the alternatives and within the station areas. Section 4.17, Parkland and Open Space, provides further information on these land uses. Because the project is located within an urban area and primarily within existing transportation rights-of-way, the Farmland Protection Policy Act does not apply.

The following subsections describe existing land uses for each segment. Allowable land uses or zoning are presented in Exhibits 4.2-1 through 4.2-6. Table 4.2-1 describes both the existing and future allowable land uses at each proposed project station, based on information from the comprehensive plans of each jurisdiction, and indicates where zoning represents a change from the existing land use. The percentages are estimates of the amount of land within the 0.5-mile station vicinity and based on information illustrated in Exhibits 4.2-1 through 4.2-6 and information taken from the comprehensive plans of each jurisdiction. Section 4.3, Economics, includes information on projected residential units and employees within 0.5 mile of the proposed stations. All land uses have been generalized into dominant land use categories (single-family, multifamily, commercial, office, mixed use, industrial, and parkland) so that the land use could be presented consistently among jurisdictions to the extent possible.

4.2.2.1 Segment A

Segment A begins in the Seattle Transit Tunnel located in a historic district (Seattle Chinatown Historic District). This area is an urban environment consisting of high-density residential, office, and commercial/industrial land uses. Continuing along I-90, immediately adjacent are Judkins Park, Sam Smith Park, and the I-90 Trail. Beyond the parkland use is a residential area of Rainier Valley, which consists of low-density single-family and multifamily housing with commercial establishments on the primary arterial of Rainier Avenue. East of the Mount Baker Tunnel, I-90 crosses Lake Washington on the way to Mercer Island. Current zoning shown in Exhibit 4.2-1 includes a mixture of single-family, multifamily, and commercial zones.

Suburban, low-density, single-family residential accounts for approximately 75 percent of the existing land use on Mercer Island, and the remaining 25 percent includes parkland, multifamily residential, and the Town Center on the south side of I-90 between 76th Avenue SE and SE Island Crest Way**.** The Town Center has a mix of multifamily residential, commercial, and office businesses, including a number of recently constructed mixed-use developments. There are no major institutions near the study area. Current zoning is shown in Exhibit 4.2-2 and includes single-family, multifamily, and the Town Center zones. The I-90 right-of-way is zoned public institution on Mercer Island. The Town Center zone allows for higher-density development, thereby making the area more pedestrian-friendly and providing easy access to the adjacent Mercer Island Park-and-Ride garage and transit stops.

4.2.2.2 Segment B

The south portion of Segment B is dominated by the large Mercer Slough Nature Park, framed to the west by a suburban residential community of low-density single-family residential and no commercial uses. North of Mercer Slough and the "Y" intersection of Bellevue Way SE and 112th Avenue SE, land uses vary. To the west, following Bellevue Way SE, single-family and multifamily housing are interspersed with some pockets of commercial retail. From Bellevue Way SE north along 112th Avenue SE, to the west are single-family and multifamily residential uses, while office complexes border the east side of 112th Avenue SE to I-405. To the east, Mercer Slough Nature Park is bounded by a strip of multifamily residential, office, and a small pocket of industrial uses adjacent to the former BNSF Railway and I-405 corridors. Other than Mercer Slough Nature Park, community facilities include a few churches located on the west side of Bellevue Way SE. Exhibit 4.2-3 illustrates current zoning for the area.

TABLE 4.2-1
Generalized Land Uses Within 0.5 Mile of Stations[a]

Station Name	Associated Alternative	Existing Land Use	Allowable Land Uses (Current Zoning)	Potential Change From Existing Land Use
Segment A, Interstate 90				
Rainier	*Preferred Interstate 90 Alternative (A1)*	Urban Residential: 40% single-family, 20% multifamily, 20% commercial, 10% industrial, and 10% parkland	Urban Residential: 20% single-family, 50% multifamily, 20% commercial/industrial, and 10% parkland	Changes
Mercer Island	*Preferred Interstate 90 Alternative (A1)*	Suburban Residential: 50% single-family, 25% Redmond Town Center, 15% parkland and right-of-way, and 10% multifamily	Suburban Residential: 50% single-family, 25% Town Center, 15% parkland and right-of-way, and 10% multifamily	No change
Segment B, South Bellevue				
South Bellevue	*Preferred 112th SE Modified (B2M),* and Bellevue Way (B1), 112th SE Modified (B2A), 112th SE Elevated (B2E), 112th SE Bypass (B3) Alternatives	Suburban Residential: 50% single-family and 50% parkland	Suburban Residential: 50% single-family and 50% parkland	No change
SE 8th	*Preferred 11th SE Modified (B2M)*, 112th SE Modified (B2A), and 112th SE Elevated (B2E) Alternatives	Mix of Uses: 45% single-family, 40% office, 5% multifamily, 5% light industrial, and 5% parkland	Mix of Uses: 45% single-family, 40% office, 5% multifamily, 5% light industrial, and 5% parkland	No change
118th	BNSF Alternative (B7)	Mix of Uses: 45% office, 35% single-family, 10% parkland, 5% multifamily, and 5% light industrial	Mix of Uses: 45% office, 35% single family, 10% parkland, 5% multifamily, and 5% light industrial	No change
Segment C, Downtown Bellevue				
108th	*Preferred 108th NE At-Grade Alternative (C11A)*	Mix of Uses: 45% single-family, 10% multifamily, 25% mixed-use, and 20% office	Mix of Uses: 45% single-family, 10% multifamily, 25% mixed-use, 20% office	No change
Old Bellevue	Bellevue Way Tunnel Alternative (C1T)	Mix of Uses: 25% multifamily, 25% single-family, 25% commercial retail, 20% office, 5% parkland	Mix of Uses: 25% multifamily, 25% single-family, 25% commercial retail, 20% office, and 5% parkland	No change
Bellevue Transit Center[b]	*Preferred 108th NE At-Grade (C11A), Preferred 110th NE Tunnel (C9T)*, Bellevue Way Tunnel (C1T), 106th NE Tunnel (C2T), 108th NE Tunnel (C3T), At-Grade Couplet (C4A), 112th NE Elevated (C7E), 110th NE Elevated (C8E), 110th NE At-Grade (C9A), and 114th NE Elevated (C14E) Alternatives	Downtown: 30% office, 25% mixed-use, 15% commercial, 20% multifamily, and 10% single-family	Downtown: 30% office, 25% mixed-use, 15% commercial, 20% multifamily, and 10% single-family	No change
Hospital	*Preferred 108th NE At-Grade (C11A), Preferred 110th NE Tunnel (C9T)*, Bellevue Way Tunnel (C1T), 106th NE Tunnel (C2T), 110th NE At-Grade (C9A), and 114th NE Elevated (C14E) Alternatives	Medical/Office: 25% office, 20% commercial, 20% office-medical, 10% single-family, 10% light industrial, 10% multifamily, and 5% parkland	Medical/Commercial: 20% office, 15% commercial, 5% mixed-use, 15% office-medical, 15% multifamily, 15% housing/office, 10% single-family and 5% parkland	Changes
Ashwood/ Hospital	108th NE Tunnel (C3T), At-Grade Couplet (C4A), 112th NE Elevated (C7E),and 110th NE Elevated (C8E) Alternatives	Medical/Office: 20% single-family, 20% light industrial, 20% office-medical, 15% office, 10% commercial, 10% multifamily, and 5% parkland	Medical/Office: 25% office-medical, 20% housing/office, 20% office, 15% commercial, 5% mixed-use, 10% multifamily, and 5% parkland	Changes

TABLE 4.2-1 CONTINUED

Generalized Land Uses Within 0.5 Mile of Stations[a]

Station Name	Associated Alternative	Existing Land Use	Allowable Land Uses (Current Zoning)	Potential Change From Existing Land Use
East Main	110th NE Elevated Alternative (C8E) (*C9T*, C2T, C3T, C4A, C7E, and C9A with connection to B3, B3 - 114th Extension Design Option, or B7)	Suburban Residential/Urban: 40% office, 25% single-family, 15% mixed-use, 5% commercial service, 10% multifamily, and 5% parkland	Suburban Residential/Urban: 40% office, 25% single-family, 15% mixed-use, 5% commercial service, 10% multifamily, and 5% parkland	No change
Segment D, Bel-Red/Overlake				
120th	*Preferred NE 16th At-Grade (D2A),* NE 16th Elevated (D2E), and NE 20th (D3) Alternatives	Industrial: 100% industrial distribution centers	Mix of Uses: 45% housing/office, 20% medical-office, 10% housing/retail, 10% housing, 10% commercial, and 5% King County Metro base	Changes
130th	*Preferred NE 16th At-Grade (D2A),* NE 16th Elevated (D2E), and NE 20th (D3) Alternatives	Industrial: 100% industrial distribution centers	Mix of Uses: 30% housing/retail, 25% commercial, 20% housing, 15% housing/office, and 10% medical-office	Changes
Overlake Village	*Preferred NE 16th At-Grade (D2A),* NE 16th Elevated (D2E), and NE 20th (D3) Alternatives	Mix of Uses: 40% commercial, 40% office, 10% multifamily, 5% single-family, and 5% medical institution	Mix of Uses: 45% housing/retail/commercial, 40% office, 10% multifamily, and 5% single-family	Changes
Overlake Transit Center	*Preferred NE 16th At-Grade (D2A),* NE 16th Elevated (D2E), NE 20th (D3), and SR 520 (D5) Alternatives	Office Campus: 80% office, 15% multifamily, and 5% single-family	Office Campus: 80% office, 15% multifamily, and 5% single-family	No change
Segment E, Downtown Redmond				
Downtown Redmond Station	*Preferred Marymoor Alternative (E2)*	Mix of Uses: 65% commercial/retail, 25% parkland, 5% multifamily, and 5% single-family	Mix of Uses: 65% commercial/ retail, 25% parkland, 5% multifamily, and 5% single-family	No change
Redmond Town Center	Redmond Way (E1), E2 - Redmond Station Design Option*, and* Leary Way (E4) Alternatives	Mix of Uses: 65% commercial/retail, 25% parkland, 5% multifamily, and 5% single-family	Mix of Uses: 65% commercial/retail, 25% parkland, 5% multifamily, and 5% single-family	No change
SE Redmond	*Preferred Marymoor (E2),* Redmond Way (E1), and Leary Way (E4) Alternatives	Mix of Uses: 45% parkland, 25% light industrial, 15% commercial, and 15% commercial/retail	Mix of Uses: 45% parkland, 25% light industrial, 15% commercial, and 15% mixed use	No change
Redmond Transit Center	E2 - Redmond Station Design Option	Mix of Uses: 60% commercial/ retail/ housing, 15% parkland, 10% multifamily, 10% light industrial, and 5% single-family	Mix of Uses: 60% mixed use, 15% parkland, 10% light industrial, 10% multifamily, and 5% single-family.	No change

[a] Existing land use and allowable land uses are based on information from comprehensive plans and planning documents from the City of Seattle, City of Mercer Island, City of Bellevue, and City of Redmond. The information is a generalization of the information to allow comparisons between the jurisdictions. The percentage of land use is an approximation of the land uses within a half mile of the station area.

[b] Bellevue Transit Center is an aggregate of the area in general around the station since the station location varies depending on alternative

Exhibit 4.2-6 **City of Redmond Generalized Zoning Segment E**
East Link Project

4.2.2.3 Segment C

Beginning at approximately SE 6th Street and moving northward, land uses transition from the suburban-style, single-family residential area and some office and hotel uses near I-405 to the highly urbanized central business district of Downtown Bellevue, which began as an older suburban commercial core. This area has evolved from a lower-density commercial district to high-rise (over 30 stories) office and multifamily residential buildings. Downtown Bellevue is both a regional employment district and a regional shopping destination, interspersed with dense multifamily residential. Although there are numerous commercial retail shops, Bellevue Square, Lincoln Square, and The Bravern are large retail centers located in Downtown Bellevue. Segment C has several centers of activity, including the Bellevue City Hall, Meydenbauer Center, Bellevue Transit Center, the Bellevue Library, and Bellevue Downtown Park. Exhibit 4.2-4 shows that zoning consists of a concentration of office land uses surrounded by commercial land uses, with multifamily residential mixed uses in the northeast quadrant of downtown.

East of I-405, Segment C includes the major land use/community facilities of the Overlake Hospital Medical Center and the Group Health Medical Center, as well as a number of medical-related offices located north of NE 8th Street and centered along 116th Avenue NE. Commercial retail uses are located east of this medical center, with a number of automotive dealerships located both along and south of NE 8th Street. Exhibit 4.2-4 illustrates zoning for the area, which includes office, office-medical, commercial, and multifamily.

4.2.2.4 Segment D

Segment D is located within the cities of Bellevue and Redmond. The segment within Bellevue is primarily within the Bel-Red neighborhood. The City of Bellevue updated and created new policies, land use designations, and zoning for this area and adopted the changes in February 2009. These changes include amendments to the *City of Bellevue Comprehensive Plan* and the *Bel-Red Corridor Subarea Plan*; changes to the maps in the *Crossroads Subarea Plan* and *Wilburton/NE 8th Street Subarea Plan*; and changes to the Bellevue City Code for the Bel-Red neighborhood area. The intent of these changes is to transition the Bel-Red area from industrial/light industrial and commercial land uses to create more dense mixed-use development, and to encourage transit-oriented development. Bellevue conducted a feasibility analysis indicating that market forces are and will be present to support this change in land use.

On the border of Bellevue with Redmond, there is a concentration of large-box retail establishments centered on 148th Avenue NE and NE 20th Street. These uses form the western border of Redmond's Overlake Village inside the Overlake neighborhood and transition to office-related uses.

The City of Redmond adopted its *Redmond Comprehensive Plan*, the *Overlake Neighborhood Plan*, and the *Redmond Community Development Guide* in December 2007 and has also recently updated the *Overlake Neighborhood Plan*. These adopted and updated plans allow for an increased level of development within the Overlake Village area. The changes will allow a greater mix and density of office and commercial uses and will provide more urban residential uses to support a mixture of mobility choices. Inside Overlake Village, the relocation of the Group Health Medical Center (relocated to the medical campus in Segment C), has opened up a 26-acre site for redevelopment just east of 152nd Avenue NE. This area is planned for 9- to 12-story mixed-use developments. Exhibit 4.2-5 shows the updated zoning for both the Bel-Red and Overlake Village areas. On the northeast end of Segment D adjacent to the Overlake Transit Center, Microsoft World Headquarters has approximately 39,000 employees located in a number of buildings west and east of SR 520.

4.2.2.5 Segment E

Segment E parallels SR 520 north and east into the Downtown Redmond area. Beginning with office campuses of 3- to 4-story office buildings, including Microsoft, the land uses transition to suburban low-density single-family residential and then to multifamily residential upon reaching West Lake Sammamish Parkway NE and entering Downtown Redmond. King County's Marymoor Regional Park forms the southern boundary of Downtown Redmond. The land uses in downtown are generally mixed with multifamily residential, commercial retail shopping, and mid-rise office complexes. The former BNSF Railway corridor divides the newer Redmond Town Center commercial district from the older downtown shopping district. Redevelopment is occurring within the northwest portion of Downtown Redmond around the Redmond City Hall and the Redmond Transit Center. Southeast of Downtown Redmond, the land uses change considerably. South of the SR 202 and SR 520 interchange, uses include light industrial/ manufacturing. Northeast and across SR 202, there are large big-box retail establishments. Exhibit 4.2-6 illustrates how Downtown Redmond permits a variety of commercial retail and service uses, as well as multifamily residential uses.

4.2.2.6 Maintenance Facility Surroundings

In Segment D, the 116th (MF1), BNSF (MF2), and SR 520 (MF3) Maintenance Facilities are all located within the Bel-Red neighborhood. Existing land uses associated with MF1 are medical offices and some residences to the west, but otherwise it is surrounded by light industrial uses and the former BNSF Railway corridor. MF2 land uses are related to light industrial, and MF3 includes a mixture of commercial service and retail and office-related uses. As described above, zoning in the Bel-Red neighborhood has recently been updated to move away from industrial land uses. Zoning is the same as described above in Table 4.2-1 for the 120th and the 130th Stations. Within Segment E, the existing land uses and current zoning (Exhibit 4.2-6) around the SE Redmond Maintenance Facility (MF5) are light industrial and manufacturing.

4.2.3 Environmental Impacts

This section discusses the project impacts on the existing and allowable future land use patterns and consistency of the alternatives with regional, state, and local policies. The potential direct and indirect impacts from project operation and construction are based on the following definitions:

- **Direct impacts.** Direct land use impacts would occur in locations where the East Link Project requires private or public property acquisitions for the project alternatives, stations, traction power substation (TPSS), maintenance facility locations, or other transit support facilities. The property acquired would be permanently converted to a transportation-related use. The property acreage is not equal to those quantities found in Section 4.1, Acquisitions, Displacements, and Relocations, of this Final EIS, because there are areas where large property acquisition would be required, but only portions would be permanently converted to transportation uses. This situation occurs for staging areas and some properties where the proposed route bisects a large property that can later be redeveloped. Direct impacts also include proximity impacts (noise and visual impacts) that could cause changes in adjacent land uses.
- **Indirect impacts**. Indirect land use impacts are related to the development and/or redevelopment of land near any of the East Link Project facilities (i.e., light rail line, stations, maintenance facilities, and traction power substations) to uses other than those currently allowed based on current zoning and land use code. These changes would only be allowed to occur when the jurisdictions enact changes in their existing zoning and land use codes to allow for such development and/or redevelopment. One such indirect impact could be transit-oriented development consisting of higher-density mixed-use development, typically around the proposed stations. Negative indirect impacts could be that residential or office uses around a proposed maintenance facility become less desirable, and therefore, property owners would request rezoning for light industrial.
- **Construction impacts**. These include impacts related to temporary land use impacts resulting from construction easements and staging areas and noise, air, visual resources, or congestion on adjacent land uses.

Direct impacts from property acquisitions are described in Section 4.1, Acquisitions, Displacements, and Relocation. Indirect impacts are assessed as the potential for transit-oriented redevelopment at each station and the compatibility of zoned uses with proposed project alternatives and associated facilities. Proximity and construction impacts were determined based on the findings of other environmental elements, including Chapter 3, Transportation Environment and Consequences, and Sections 4.3, Economics; 4.5, Visual and Aesthetic Resources; 4.6, Air Quality; and 4.7, Noise and Vibration.

4.2.3.1 No Build Alternative

The No Build Alternative would not displace any residents or businesses. However, this alternative is inconsistent with many of the regional land use and transportation policies by not instituting a high-capacity transit system connecting the region’s highest-growth centers, nor is it consistent with the local plans that encourage increased density and/or transit-oriented development patterns in anticipation of light rail service. The PSRC policies related to focused and compact growth, frequent transit service, connecting urban centers, and transportation alternatives to the single-occupant vehicle would be either not fully implemented, or only partially implemented. Therefore, the No Build Alternative would constrain transportation options, leading to more traffic congestion where higher density is planned or causing less dense development patterns in the growth centers. This reaction could cause a shift to more automobile-oriented land use patterns, which are typically more spread out and less dense than transit-oriented development patterns. This might lead to developing more land area and creating longer travel patterns.

4.2.3.2 Impacts during Operation

This section evaluates the project's consistency with land use plans and policies and identifies direct impacts common to all alternative, indirect impacts related to transit-oriented development, and direct and indirect impacts by segment.

Consistency with Land Use Plans and Policies

Regional, state, and local land use plans in the study area share the goal of improving transit accessibility and encouraging transit usage by concentrating mixed land uses within the project corridor in areas that the jurisdictions have identified. The project would connect employment centers and provide for uninterrupted access among the four jurisdictions in the corridor. Sound Transit reviewed regional, state, local, and major institution master plans to identify goals and/or policies applicable to the East Link Project to determine whether the project is consistent with the applicable plans. The route and station alternatives are generally consistent with regional plans and polices in the study area. There are, however, certain inconsistencies with local zoning. For example, in the City of Bellevue Land Use Code, "light rail transit facilities" are not defined and are not called out as a permissible use in any zone; "rail transportation" is allowed as a conditional use in all zones except the downtown zones, where it is expressly not allowed as either a permitted or conditional use; a maintenance facility might not be allowed in the Bel-Red corridor. In the *Redmond Community Development Guide*, the definition of "public facilities" that are permitted in downtown and other zones does not explicitly include transit facilities.

The East Link Project complies with goals and polices identified in PSRC's *VISION 2040* by providing a regional transit system serving a growing transportation need for planned density of residential and employment uses within designated urban areas. *VISION 2040* is a regional strategy that provides the environmental framework, growth strategies, and policies to accommodate the 1.7 million additional people and 1.2 million additional jobs expected in the Puget Sound region by 2040. *VISION 2040* identifies focusing the growth in regional growth centers—which are areas of higher densities of population and employment served by multimodal transportation that provide opportunities for arts, civic activity, commerce, and recreation. Downtown Bellevue, Overlake, and Redmond in the East Link Project study area are identified in *VISION 2040* as regional growth centers. The East Link Project is also identified in PSRC's *Transportation 2040* plan and the 2010-2013 *Transportation Improvement Plan* (PSRC, 2010b).

Local planning documents focus on the types of land uses permitted within zones and the scale to which development is allowed to occur within these zones. The East Link Project would increase transit level of service and linkages with other jurisdictions and regional destinations. Development around station areas in lower- density residential areas is not expected to encourage incompatible commercial or office development because the applicable plans and codes preclude such development. In those areas where the local jurisdictions have adopted land use plans, policies, and development regulations to facilitate higher density (including mid- and high-density mixed use of multifamily residential, commercial, and office development), also known as transit-oriented development, the East Link Project would be consistent with the goals and policies.

In addition, the GMA requires that zoning be consistent with comprehensive plans as well as prohibits local governments from precluding the siting of essential public facilities either through its comprehensive plans or zoning. The East Link Project is a "regional transit authority facility" and is, therefore, explicitly recognized as an essential public facility in the GMA (RCW 36.70A.200). Once Sound Transit's routing decision has been finalized, each jurisdiction has a "duty to accommodate" the East Link Project in their land use plans and development regulations.

The Cities of Bellevue and Redmond have recently amended their comprehensive and neighborhood plans to allow a greater density of land uses and a mixture of land uses within the Bel-Red corridor in Bellevue and the Overlake neighborhood in Redmond. Except for the SR 520 Alternative (D5), the East Link Project would be consistent with the desired land use changes and densities. Alternative D5, although consistent with a number of the regional plans and policies, would not support planned changes for the Bel-Red neighborhood. Further, Alternative D5 does not include any stations in the Bel-Red corridor, and is not consistent with the cities' goals and polices identified in the Bel-Red Subarea plan.

King County and the Cities of Seattle and Redmond have recently amended their shoreline master programs to specifically address light rail as an allowed use within the shoreline environment. The Cities of Mercer Island and Bellevue are in the process of updating their shoreline management plan to directly address light rail as well.

Although not part of the comprehensive plan, the city councils of Mercer Island and Bellevue have adopted information in the form of principles or practices related to light rail. The City of Mercer Island adopted the *Design Principles for Mercer Island Town Center Light Rail* in 2008, which includes 12 principles that Sound Transit should incorporate into the East Link Project at the Mercer Island Station. Principles relate to the station design and how the station ties into the Town Center area on Mercer Island.

The City of Bellevue's *Best Practices for Light Rail*, which was developed by a committee comprising members from four city boards and commissions, was finalized in June 2008; it includes a range of actions meant to guide light rail development in Bellevue. While the report does not specifically address any alternative being evaluated through the environmental process, the *Preferred Alternatives* in Segments B, C, and D are consistent with Bellevue's plans and policies. Topics addressed in the *Light Rail Best Practices* document include Community and Neighborhoods; Community Involvement; Connecting People to Light Rail; Land Use; Street Design and Operations; Elevated, At-Grade, and Tunnel; Property Values; Station Security; and Construction Impacts and Mitigation. The range of actions includes several policies adopted by the City Council and amended into the comprehensive plan. These policies are identified in Table F4.2-1 in Appendix F4.2, Land Use Plans and Policies.

Three alternative maintenance facilities are being considered in Segment D (116th [MF1], BNSF [MF2], and SR 520 [MF3] Maintenance Facilities). The *Bel-Red Subarea Plan* indicates that new light industrial land uses would no longer be allowed within the Bel-Red area; however, the *Bel-Red Subarea Plan* does identify the potential need for a maintenance facility in the Bel-Red area and that the City of Bellevue would coordinate with Sound Transit on placing a maintenance facility if one is needed in the subarea. The Bel-Red Subarea zoning designations applicable to all three Segment D maintenance facility locations include "Rail Transportation: Right-of-Way, Yards, Terminals, Maintenance Shops" as a conditional use in those zones (Bellevue City Code 20.25D.070). The SE Redmond Maintenance Facility (MF5) is consistent with existing plans and policies for the proposed locations. Further information on these plans, goals, and polices, and discussion of the project's consistency with them, is provided in Appendix F4.2.

Direct Impacts Common to All Build Alternatives

Aside from Segment A, all of the East Link Project alternatives would acquire properties to allow for project construction. Although property acquisitions, displacements, and the land use conversions would occur before project construction, they would be considered an operational impact because of their potential long-term effects. Any property acquisition would convert existing land uses to public right-of-way (which is a transportation-related use) to be used for East Link Project construction and operation (i.e., light rail track, stations, traction power substations, or maintenance facilities).

Although the final routing of the East Link Project is not known, the land to be acquired would constitute only a small portion of the total residential, commercial, and public land in the project vicinity and would not result in material changes in the regional or local land use or development patterns. Most of the East Link Project alternatives being considered follow existing transportation corridors, which reduces the amount of right-of-way required for construction. In areas where the project would only partially acquire or in areas that would be used for construction staging, the land could be restored to its previous land use or redeveloped with an allowed use under current zoning. Such actions would reduce the amount of property converted to public right-of-way.

It is important to note that a number of the partial acquisitions would be considered "sliver" acquisitions because they are small in size and would not affect property use. Overall, the amount of land converted to public right-of-way and the number of displacements caused by full acquisitions would result in greater impacts on land use than the number of partial acquisitions. Of the known visual and noise impacts associated with the route alternatives, none would negatively affect existing or future use of the land. Refer to Section 4.5, Visual and Aesthetics, and 4.6, Noise and Vibration, for complete information on these impacts.

Table 4.2-2 shows maximum amount of zoned land that would be converted to a transportation-related use for each alternative. The range of acreage that would be required in Segments C and D accounts for the range in potential connectors from alternatives in the adjacent segment. The totals represent the amount of property that would be required outside of the existing roadway rights-of-way and includes neither staging areas required in Segment C nor areas where remnant land could be sold for redevelopment after construction. For the City of Bellevue, the range of acreage converted to a transportation-related use would be approximately .8 to 18.8 acres, which represents less than 0.1 percent of the total area of Bellevue. (Bellevue encompasses 33.9 square miles; 30.8 square miles are land and the rest water.)

SR 520 Alternative (D5)	1.4	2.7 to 5.0	5.7 to 5.9	3.7	N/A	0.7 to 1.1	**5.8 to 6.3**
Segment E, Downtown Redmond							
Preferred Marymoor Alternative (E2)	N/A	N/A	9.4	N/A	6.0	1.9	**17.3**
E2 – Redmond Transit Center Design Option	0	N/A	11.8	0	3.7	9.6	**25.1**
Redmond Way Alternative (E1)	0.2	N/A	11.8	0.7	1.6	4.1	**18.4**
Leary Way Alternative (E4)	0	N/A	5.9	0.2	1.6	3.3	**11.0**
Maintenance Facilities[a]							
MF1, 116th	0	0.4 to 10.2	10.2 to 13.9	5.4 to 13.2	N/A	5.4 to 5.5	**21.4 to 42.8**
MF2, BNSF	0	0 to 1.2	23.1 to 23.4	7.1	N/A	12.2 to 22.4	**42.4 to 54.1**
MF3, SR 520	0.6 to 18.6	0	18.4 to 22.6	N/A	N/A	N/A	**19 to 41.2**
MF5, SE Redmond	0	0.4	17.7 to 20.4	N/A	N/A	N/A	**17.7 to 20.4**

Note: Segment A would not convert any land use to transportation-related land use.

[a] For Segments C and D and the maintenance facilities, the ranges depend on the design option selected. The total area ranges reflect the amount of land converted by a specific route alternative and are not the total of all the areas within each zone. These ranges include the ranges in potential connectors from alternatives in the adjacent segment. Acreage excludes planned staging areas and portions of parcels that are anticipated to be sold after construction is complete

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

N/A Not applicable

For the City of Redmond, the range of acreage converted to a transportation-related use would be 11 to 25.6 acres, which represent less than 0.1 percent of the total area of Redmond (Redmond encompasses 17 square miles). Land use impacts at any potential interim terminus station (Ashwood/Hospital or any station farther east) would be the same whether that station is built as an interim terminus or not.

Indirect Impacts Related to Transit-Oriented Development

Light rail transit contributes to existing market forces that can increase the potential for transit-oriented development or redevelopment. Improved transit access can increase the convenience and desirability of surrounding residential, commercial, and office properties. The type of development or redevelopment near stations with available land and supportive zoning in place tends to be more intense, mixed-use development that supports high-density residential, commercial, and office-related uses.

In a number of cases, transit stations have provided an opportunity for local jurisdictions to focus redevelopment activities. Factors that affect and influence private development include local and regional market conditions and trends, zoning and other land use regulations, accessibility of credit, and interest rates. Experience around the United States, however, indicates that developing new transit facilities has often occurred concurrent with major changes in development near stations (typically within 0.25 mile of the station) (Transit Cooperative Research Program, 1996).

It has been shown that jurisdictions with supportive policies, land use controls, and direct incentives can substantially increase the amount of development or redevelopment occurring near transit stations. Near the East Link stations, surrounding parcels are already developed, and transit-oriented development, if it occurred, would be redevelopment. Transit-oriented development generally takes place under three conditions:

1. When stations are located in prime regional and community centers of activity attractive to typical market forces
2. When regional and local real estate markets are active
3. When public policies and regulations permit or encourage intensive development in station areas

The experience of other U.S. communities has demonstrated that, although light rail transit would not by itself create new development, with transit-supporting plans and policies in place, it can influence where development or redevelopment would occur and the types of development that would occur. The benefits of successful transit-oriented development have included improved mobility; increased supplies of affordable housing; increased transit ridership in a more efficient urban form; and opportunities for urban redevelopment (City of Seattle, 1998). This might result in the synergy of businesses' and employee's interest in locating within convenient access to the light rail line, leading to more dense land uses around stations and therefore resulting in increased economic activity at stations. Section 4.3, Economics, discusses the economic benefits associated with the East Link Project. Station area transit-oriented development would only occur in areas where the current land uses are light industrial. Most other stations areas are already built out per approved land uses.

Table 4.2-3 describes the ratings used by Sound Transit for the likelihood that each proposed light rail station would support indirect changes in existing land use and development patterns, resulting in transit-oriented development patterns in the station areas. The ratings shown indicate the extent to which the light rail system might support indirect land use changes within 0.5 mile of station areas under existing plans and policies. Existing transit-oriented development centers, such as the Bellevue Transit Center, were not rated as high because the density already exists and would not likely be affected by the project.

TABLE 4.2-3
Potential for Station Areas To Support Transit-Oriented Development

Ranking	Description
Low	One or more of the following factors is occurring in the station area: Not located in prime regional and/or community center, regional and local real estate markets are not active in the area, existing transit-oriented development already exists in surrounding area, and/or current plans and policies do not permit or encourage transit-oriented development in station areas.
Moderate	One or more of the following factors is occurring in the station area: Located in somewhat prime regional and/or community center, regional and local real estate market are active, and/or current plans and policies permit or encourage transit-oriented development in station areas.
High	One or more of the following factors is occurring in the station area: Located within prime regional and/or community center, regional and local real estate markets are highly active, and/or current plans and policies promote or encourage the intensive development in station areas.

Implementing the East Link Project would allow jurisdictions to implement regional policies related to high-capacity transit (Appendix F4.2) as well as those planning for increased densities, especially related to transit-oriented development. The following subsections record the specific direct and indirect impacts of the routes, stations, and maintenance facilities.

Impacts during Operation by Alternative

Segment A

No direct impacts would be associated with Preferred Alternative A1 because operation would remain within existing transportation rights-of-way.

Rainier Station

No land use changes are anticipated, and it is anticipated that the station would support the development of multifamily residential uses in the permitted zones around the station. The potential for indirect impacts related to transit-oriented development is rated low/moderate because, although current zoning allows for multifamily residential and commercial uses that would support transit-oriented development, the parks and recreation facilities surrounding the station limit the extent to which development could occur.

Mercer Island Station

The Mercer Island Station would complement the existing land uses and future land uses within the Town Center district and encourage continued density in the Town Center. Residential areas to the north are not anticipated to be affected because they are buffered by I-90, parks and trail facilities, and other uses as specified in the Mercer Island City Code. The potential for indirect impacts related to transit-oriented development would be moderate because current zoning allows for transit-oriented development, and additional capacity for more dense redevelopment exists within the Town Center district (Exhibit 4.2-2).

Segment B

Segment B alternatives would acquire residential and commercial properties. *Preferred 112th SE Modified Alternative (B2M)* would convert approximately 6.4 to 6.5 acres, depending on connection to Segment C, to transportation-related uses, most of which are currently parkland zoned as single-family and undeveloped office. *Preferred Alternative B2M* would have the lowest total number of displacements of the Segment B alternatives along Bellevue Way SE, including only one residential displacement.

Based on current design, the Bellevue Way Alternative (B1) would have the greatest number of acquisitions and displacements and would convert the greatest amount of residentially zoned property (7.9 acres). The BNSF Alternative (B7) would result in the fewest total acquisitions, but as shown in Table 4.2-2, it would result in potentially the greatest land use conversion to transportation-related uses (10.3 acres) primarily from office uses. The 112th SE Elevated Alternative (B2E) would result in the fewest displacements as well as the least amount of land that would need to be converted (see Table 4.2-2).

South Bellevue Station (*Preferred Alternative B2M* and Alternatives B1, B2A, B2E, and B3)

A garage would expand the number of available parking stalls to 1,400 stalls at the South Bellevue Park-and-Ride. However, expanding the parking is not expected to change any of the surrounding land uses because of strong geographic barriers, including the Mercer Slough Nature Park—a large wetland park to the north, east, and south of the station—and the established single-family residential neighborhood of Enatai located above the station and west of Bellevue Way SE. Because of these factors, the station received a low rating for transit-oriented development potential (see Table 4.2-3).

SE 8th Station (*Preferred Alternative B2M* to *Preferred Alternative C9T* and Alternatives B2A and B2E)

No direct or indirect impacts on land use are anticipated. Because of the limited potential to develop around the site and because of the single-family neighborhood to the west, the station received a low rating for the likelihood of the station to cause changes in land use related to transit-oriented development (see Table 4.2-3).

118th Station (Alternative B7)

There would be limited, low potential to develop around the 118th Station because of the adjacent land uses of Mercer Slough Nature Park and the I-405 corridor. Therefore, the station was assigned a low potential for transit-oriented development (see Table 4.2-3). This station is intended to serve as a park-and-ride site for communities to the east and west and could result in the closure of the Wilburton Park-and-Ride Lot north of the proposed station at the intersection of SE 8th Street and I-405.

Segment C

Segment C includes a number of proposed construction staging areas that could be redeveloped to a use conforming to the current zoning. For alternatives located within tunnels, land use impacts are anticipated only in the station areas and tunnel portal locations.

Property acquisitions associated with *Preferred 108th NE At-Grade Alternative (C11A)* would convert approximately 14.4 to 16.2 acres, depending on the connection from Segment B, to transportation-related uses, most of which is currently zoned commercial and office. The connection from *Preferred Alternative B2M* would result in a greater area of properties converted to a transportation-related use and results in the conversion of single family and multifamily areas.

Property acquisitions associated with *Preferred 110th NE Tunnel Alternative (C9T)* would convert approximately 10.2 to 12.6 acres to transportation-related uses, most of which is currently zoned commercial and office. Similar to *Preferred Alternative C11A*, the connection from *Preferred Alternative B2M* would result in the greatest area converted and the conversion of single-family and multifamily zoned areas. If C9T - East Main Station Design Option were selected, then it would not require any additional parcel acquisitions, and impacts on current land uses within the area would be the same.

The Bellevue Way Tunnel Alternative (C1T) would result in the most impacts related to residential-zoned areas, thereby resulting in the greatest number of residential displacements (93, which includes 62-unit, 24-unit, and 7-unit apartment complexes). Alternative C1T could potentially require the conversion of 10.4 acres of commercial, office, and multifamily land uses, which is higher than all other alternatives in Segment C (see Table 4.2-2). The 110th Avenue NE Elevated Alternative (C8E) would result in the lowest amount of land (4.7 acres) converted to transportation-related uses (see Table 4.2-2).

Old Bellevue Station (Alternative C1T)
No change in land use is anticipated at this station because the surrounding area is zoned for uses that would support the East Link Project. This station received a low to moderate rating to influence new transit-oriented development because of the already dense commercial development in the surrounding area and the nearby single-family residential zone.

108th Station (*Preferred Alternative C11A*)
There is low potential for transit-oriented development south of the 108th Station and Main Street because the area is zoned single-family and includes the residential Surrey Downs neighborhood. North of the station and Main Street are mixed use and office uses in Downtown Bellevue that could increase in density. New development might be attracted north of the 108th Station. This area is considered to have low to moderate potential for transit-oriented redevelopment.

East Main Station (*Preferred Alternative C9T* and Alternatives C2T, C3T, C4A, C7E, and C8E)
Remaining lands adjacent to the station would be available to return to uses conforming to zoning; however, no additional changes in land use are anticipated as a result of this station. This station received a low rating for transit-oriented development because of the single-family residential uses to the west and I-405 on the east, which limit the extent to which redevelopment could occur.

Bellevue Transit Center Station (All Segment C alternatives)
Because many of the land uses around the station locations associated with the various alternatives are already high density, the East Link Project would not influence or indirectly change land use patterns, and therefore these locations received a low potential to influence transit-oriented development. Instead of influencing transit-oriented development the stations would help serve existing land uses with improved mobility options, but the stations associated with Alternative C7E and 114th NE Elevated Alternative (C14E) are located farther away and may not influence any additional changes or improve mobility options as greatly as the other alternatives that have stations closer to the existing Bellevue Transit Center.

Hospital Station (*Preferred Alternatives C11A* and *C9T* and Alternatives C1T, C2T, C9A, and C14E)
This station may influence redevelopment opportunities for limited, mixed-use developments related to multifamily and office/medical office-related uses occurring around the station. By providing increased access and mobility, the station would support the major land use in the area (Overlake Hospital and Group Health Medical Centers) and the surrounding supporting uses. Because of recent development at the hospital campuses and relatively limited land area around the station, the station received a low/moderate rating for ability to influence redevelopment related to transit-oriented development.

Ashwood/Hospital Station (Alternatives C3T, C4A, C7E, and C8E)
The potential for redevelopment with the Ashwood/Hospital Station is similar to that described above for the Hospital Station. The potential for development around this station resulted in it receiving a low to moderate rating for redevelopment attributed to the station.

Segment D
All of the Segment D alternatives would require property acquisitions and the displacement and relocations of businesses, but there would be no

residential displacements associated with any of the alternatives.

Preferred NE 16th At-Grade Alternative (D2A) would convert 27.4 acres to a transportation-related use, with most the land currently zoned light industrial and commercial. The Alternative D2A - 120th Station Design Option would result in the same land use conversion as *Preferred Alternative D2A,* and the Alternative D2A - NE 24th Design Option would result in 28.7 acres being converted to a transportation-related use. *Preferred Alternative D2A* would be integrated with planned developments around the stations. *Preferred Alternative D2A* would be consistent with the changes in the Bel-Red neighborhood and would support the portions of the City of Bellevue SubArea Plan that address light rail through the corridor, with stations located at 120th and 130th Avenues NE.

The other Segment D alternatives would include a range in the amount of land that would be converted, depending on the connection from Segment C. The NE 20th Alternative (D3) would result in the greatest number of potential business displacements (64 to 72) and the greatest amount of land that could be converted to a transportation-related use (35 to 37.6 acres). The SR 520 Alternative (D5) would result in the least land converted to a transportation-related use (11.1 to 13.5 acres), with the majority being land currently zoned light industrial.

Alternative D5 does not include any stations within the Bel-Red neighborhood. Growth in the Bel-Red area would be dependent on other forms of transit, which would be less consistent with Bellevue's desired densities and planned land use development in this area.

120th and 130th Stations (*Preferred Alternative D2A* and Alternatives D2E and D3)
Negative land use impacts are not expected around these station areas. The City of Bellevue is encouraging redevelopment of the industrial areas to mixed use, high-density employment and residential centers. The stations have a moderate to high rating for a potential to influence development because of the land use changes that encourage development supportive of transit-oriented development (see Table 4.2-3).

Overlake Village Station (All Segment D alternatives)
Like the stations located in Bellevue, a station located within the Overlake Village area would support the City of Redmond to fully implement the recently adopted land use changes and allow for a mixed-use, high-density employment and residential center at Overlake Village. Therefore, the station locations received a moderate to high rating for potential to influence transit-oriented development. The station associated with *Preferred Alternative D2A* along SR 520 would be located farther from the area that could be redeveloped, which may have a lower potential to influence development than the other station alternatives.

Overlake Transit Center Station (All Segment D alternatives)
No change is anticipated on land uses surrounding the station. However, the station would support the existing land use and would increase mobility for expanding numbers of Microsoft and other nearby office employees. The station was assigned a low potential to influence land use changes related to transit-oriented development because of the existing development and the current zoning in the area.

Segment E
All of the alternatives in Segment E would require property acquisitions and the displacement and relocations of businesses and residences.

The property acquisition associated with *Preferred Alternative E2* would convert approximately 17.3 acres to a transportation-related use (see Table 4.2-2). The majority of the area converted is currently zoned light industrial and single family residential.

The E2 - Redmond Transit Center Station Design Option would result in the most the most land that would potentially be converted to a transportation-related use (25.1 acres) (see Table 4.2-2). The Redmond Way Alternative (E1) and the Leary Way Alternative (E4) would have similar amounts of property acquisitions and displacements, and Alternative E4 would result in the least land (11.0 acres) that would be converted to a transportation-related use.

Downtown Redmond Station (*Preferred Alternative E2*)
This station would be located north of the Redmond Town Center Station and closer to the northern areas of Downtown Redmond. It would be a terminus station for *Preferred Alternative E2*. Much of the area around the Downtown Redmond Station has recently been redeveloped with mixed-use and commercial buildings; therefore, there is limited potential for new transit-oriented development directly adjacent to this station. Some properties farther away, however, could be considered for redevelopment due to their proximity to this station; as a result this station has a moderate potential for transit-oriented development.

Redmond Transit Center Station (E2 - Redmond Transit Center Design Option)
The Redmond Transit Center Station would not alter the existing or future land use patterns and would offer additional mobility options for existing mixed-use development being developed near the station. This is a potential terminus station for *Preferred Alternative E2*. This station has a moderate potential for transit-oriented development based on the information in Table 4.2-3 and the King County Metro Transit Center.

Redmond Town Center Station (Alternatives E1 and E4)
This station would not alter existing development patterns. The station area would support continued development of mixed uses and additional buildout consistent with current zoning. Therefore, it was assigned a moderate potential for additional transit-oriented development based on Table 4.2-3.

SE Redmond Station (*Preferred Alternative E2* and Alternatives E1 and E4)
The SE Redmond Station is the proposed terminus station for both Alternatives E1 and E4, and it would be the first station in Redmond for *Preferred Alternative E2*. This station, planned to be a park-and-ride station for communities to the north and east, would not cause the surrounding land uses to deviate from industrial zoning. The station would be located in different areas with the three Segment E alternatives, and all locations were assigned a low/moderate potential for transit-oriented development based on Table 4.2-3 and because of newer developments (i.e., Whole Foods retail center, Fred Meyer, Home Depot) around the station locations.

4.2.3.3 Impacts During Construction

Impacts Common to All Build Alternatives

Construction of the East Link Project would result in temporary impacts on existing land uses as a result of construction activities (e.g., earthmoving, truck traffic). The temporary impacts would include potential increases in noise levels, dust, traffic congestion, visual changes, and increased difficulty accessing residential, commercial, and other uses. Refer to Chapter 2, Alternatives Considered, for information on methods of construction for the alternatives. Although some businesses may experience hardship during construction, this would not affect land use type unless the property became vacant. For more information on impacts, including impacts on the existing uses (i.e., businesses and residences), see Chapter 3, Transportation Environment and Consequences, and Sections 4.3, Economics; 4.4, Social Impacts, Community Facilities, and Neighborhoods; 4.5, Visual and Aesthetic Resources; 4.6, Air Quality; and 4.7, Noise and Vibration.

Construction would also require easements beyond the property acquisition needed within the project limits. These easements might affect portions of property on residential, commercial, industrial, and public properties in all segments except Segment A (because this alternative is located largely within an existing Washington State Department of Transportation [WSDOT] I-90 right-of-way). The easements are temporary and would be returned to preconstruction conditions upon completion. Following construction, redevelopment of remaining parcels would occur consistent with land use zones for the parcels. Section 4.1, Acquisitions, Displacements, and Relocations, provides more information on the methods to be implemented to compensate those affected.

Segment A

There would be no additional impacts in Segment A other than those described above. Impacts on the surrounding land uses would be minimal because construction would occur almost entirely within the center of I-90. In addition, construction staging would also occur within the existing I-90 right-of-way.

Segment B

There are no additional impacts from Segment B alternatives other than those described above; however, the extent of the temporary impacts discussed under Impacts Common to All Build Alternatives would vary depending on the alternative.

Preferred Alternative B2M would require additional construction easements within Mercer Slough Nature Park, and have impacts occurring over a potentially larger area because the trackway would be located farther east of Bellevue Way SE to its intersection with 112th Avenue SE for connections to either *Preferred Alternative C11A* or *Preferred Alternative C9T*. These temporary construction easements would temporarily displace the blueberry farm and the Eastside Heritage Center, which is located in the Winters House. All areas could be returned to their prior use after construction, and no permanent change in land use would occur. *Preferred Alternative B2M to C11A* would include construction activities closer to the residences west of 112th Avenue SE because the trackway would be located in the median, whereas *Preferred Alternative B2M to C9T* would remain east of 112th Avenue SE. However, the construction activities associated with *Preferred Alternative B2M to C11A* is not anticipated to result in any additional impacts.

Alternative B1 would result in temporary impacts on a number of properties located adjacent to construction of the at-grade trackway in the center of the roadway, which has the potential to affect the accessibility of land uses west and east of Bellevue Way SE. Many driveways are more likely to be affected with Alternative B1 when compared with *Preferred Alternative B2M,* including a few businesses that would be affected by limitation in access. Alternative B7 would have the fewest impacts on properties and business access because a majority of the work would occur within existing rights-of-way and away from adjacent land uses. The extent of the impacts from Alternative B1 would be similar for Alternatives B2A, B2E, and B3 because these alternatives follow roughly the same route and would require the same construction methods for much of the alternative length. The B3 - 114th Design Option is similar to other Segment B alternatives along Bellevue Way SE and 112th Avenue SE, but it would curve away and avoid some of the residences along 112th Avenue SE.

Segment C

The extent of the temporary impacts discussed under Impacts Common to All Alternatives would vary depending on the alternative and its connection from Segment B. All of the Segment C alternatives except C1T can connect to Alternatives B3, B3-114th Extension Design Option, or B7, and impacts on land uses between SE 6th Street and Main Street would be similar. For the most part, the connection would be elevated and access points to adjacent land uses would be maintained. With these connections, no adjacent residential land uses would be affected until the alternatives reach Main Street.

With *Preferred Alternative C11A* connection from *Preferred Alternative B2M*, construction activities along 112th Avenue SE and Main Street would primarily be outside of the roadway right-of-way and adjacent to residential land uses within the construction area. Construction would limit access to the residential Surrey Downs neighborhood due to the required closure of SE 4th Street, but access would be maintained at other points. Construction would also occur in the center of the 108th Avenue NE between Main Street and NE 6th Street, restricting access to businesses on either side to right-in, right-out only.

The connection from Alternatives B3 or B7 would result in less construction activity adjacent to Surrey Downs neighborhood and more on adjacent businesses, and the construction impacts along Main Street would be similar.

East of the Bellevue Transit Center Station the trackway would primarily be outside of the dense land use in Downtown Bellevue and within the existing rights-of-way of NE 6th Street, I-405, and the former BNSF Railway corridor. Impacts would be similar to those described above under Impacts Common to All Alternatives.

Construction activities for *Preferred Alternative C9T* along 112th Avenue SE would primarily be outside of the roadway right-of-way, similar to *Preferred Alternative C11A,* with the primary difference between the alternatives being the closure of SE 1st Street limiting access to the Surrey Downs neighborhood. Similarly, the connections from B3 or B7 would reduce construction along Surrey Downs residential areas.

East of the Bellevue Transit Center Station, *Preferred Alternative C9T* would be the same as *Preferred Alternative C11A.*

Preferred Alternative C9T would include cut-and-cover activities to construct the tunnel between Main Street and NE 6th Street, west of 112th Avenue NE. Cut-and-cover activities can result in the greatest impacts on the adjacent land uses because this method requires relatively deep excavation and restricts access until covers can be installed over the excavated area. The exact closure methods used (i.e., partial closure of roadway or full closure of roadway) would be decided prior to construction. When the cut-and-cover activities are complete and the excavated area is covered, vehicle access would be restored and remaining construction activities would have minimal impacts. The impacts associated with cut-and-cover would be similar to those described under Impacts Common to All Alternatives; however, the impacts would likely be more adverse than either at-grade or elevated construction because of the nature of construction activities required.

Alternatives C1T, C2T, and C3T (tunnel alternatives) all would include cut-and-cover activities, resulting in similar impacts as those described under *Preferred Alternative C9T*. Alternatives C1T and C2T would require more cut-and-cover activities than *Preferred Alternative C9T*. Impacts associated with Alternative C1T could be less severe than with Alternative C2T because construction could occur in the middle lanes of traffic, thereby allowing right turns in and out along Bellevue Way SE and restricted left turns until the roadway is covered. Alternative C2T would likely require either a partial closure or full closure of 106th Avenue NE through Downtown Bellevue, depending on construction method; C2T would likely require detours and temporary loss of access to some adjacent land uses.

The Alternative C3T tunnel would be entirely bored except for the portals (Surrey Downs Park, East Main or north boundary of Surrey Downs residential area) and the Bellevue Transit Center Station, and construction impacts with this alternative would result in the least degree of impacts because cut-and-cover impacts would occur in fewer locations and be less severe than the other tunnel alternatives. The tunnel alternatives would have additional truck traffic related to the hauling of materials to allow construction activities to occur.

Alternative C9A would have the shortest duration of construction impacts among Segment C alternatives and would likely result in the fewest impacts on surrounding land uses. The connection from Alternative B2A would require construction activities within 112th Avenue SE and likely would result in limiting access to right-turn in and out of the roadway. Construction activities north of Main Street would occur at-grade along 110th Avenue NE, limiting access to either left- or right-turn in and out. Impacts would be the same as those described under *Preferred Alternative C11A* for the trackway east of the Bellevue Transit Center Station.

Alternative C4A would result in impacts similar to Alternative C9A, to approximately SE 6th Street, but it would affect land uses on two streets north of Main Street: 110th Avenue NE and 108th Avenue NE. However, it is likely that construction requiring substantial street closures would occur on one street and not on the other street, which would limit the impacts on surrounding land uses, compared to construction that is conducted concurrently.

Alternatives C7E, C8E, and C14E would have similar impacts. Construction activities would still permit access to the land uses, except during construction of the elevated structures that would require temporary street or lane closures (for safety and to place the elevated structure) and would limit access to adjacent land uses. Alternative C8E would result in a greater impact on single-family and multifamily land uses adjacent to 110th Avenue NE and NE 12th Street.

For most of the project, remnant parcels from property acquisition or vacant lots would be used for staging areas, except in Segment C, where specific staging areas have been identified, because few open land areas exist in that segment. For the most part the identified staging areas are associated with commercial uses or zoned commercial in Downtown Bellevue. *Preferred Alternatives C11A* and *C9T* would include staging areas along 112th Avenue SE associated with multifamily residential. The staging areas would change existing land uses during construction. However, in most situations, staging areas would be available for redevelopment consistent with current zoning. Refer to Section 4.1 for information on the number of displacements associated with the staging areas. Temporarily, land uses adjacent to the staging area would be affected and could result in some temporary closures or in businesses relocating (refer to Section 4.4 and 4.5 for more discussion on impacts on businesses and proposed mitigation).

The following describes staging areas that may cause changes in land uses upon project completion. For many areas in Segment C, the land uses are associated with commercial uses that would remain after construction; therefore, no impacts on land use are anticipated in these areas. Depending on the sensitivity of the surrounding land uses, a fence or barrier could surround the staging area to provide a buffer to adjacent land uses from noise and visual impacts. All Segment C alternatives except Alternative C1T have a possible connection from Alternative B3, the B3 - 114th Design Option, or B7; these alternatives would require a staging area on the site of the Red Lion Hotel. For all alternatives except *Preferred Alternative C11A* and Alternative C14E, the staging area would become the location of the East Main Station and change the existing land use. Under *Preferred Alternative C11A* and Alternative C14E, the land would likely continue to be zoned for commercial uses and redeveloped after construction.

Staging from *Preferred Alternative B2M* to *C11A* and *C9T*

The staging areas on the west side of 112th Avenue SE and the south side of Main Street would indirectly affect the surrounding land uses through noise and visual impacts during construction. After construction, part of this staging area south of Main Street could be used by the City of Bellevue to construct a transition park south of Main Street, which would buffer residences from the downtown core. Policy S-DT-125 in the Bellevue Comprehensive Plan discusses creating open space buffers to provide transition from downtown to the surrounding residential neighborhoods (City of Bellevue, 2006). In addition, the area along 112th Avenue SE would provide a greenbelt or park between the light rail and the adjacent neighborhood.

Staging from Alternative B2A to Alternatives C2T and C3T

The staging area on the north side of Surrey Downs Park would directly remove the civic use as a courthouse, if it has not previously moved, and a portion of the unimproved park, which would result in temporary indirect impacts on adjacent residential land uses during construction activities. However, there is the potential for the City of Bellevue to redevelop the staging area after construction to its intended future use as a park, free of the courthouse structure.

Staging from Alternative B2E to Alternatives C2T, C3T, and C9A
The staging areas adjacent to Main Street would indirectly affect the surrounding land uses through noise and visual impacts during construction. Similar to *Preferred Alternatives C11A* and *C9T*, part of this staging area could be used by the City of Bellevue to construct a transition park south of Main Street after construction to buffer residences from the downtown core or they could redevelop consistent with local zoning.

Staging Area at Alternatives C3T, C4A, and C8E
These alternatives would disrupt McCormick Park north of NE 12th Street as well as residences north of the park because of noise and visual impacts. The lands used for staging are intended to be returned to a restored McCormick Park, including the acquired properties. This is a change in existing zoned lands but upholds the value of a transition park to buffer residents from the infrastructure.

Segment D

There would be no additional impacts other than the common impacts described above; however, the extent of the temporary impacts discussed under Impacts Common to All Alternatives would vary depending on the alternative. Because the Segment D alternatives are located adjacent to land uses that are primarily industrial and commercial, the extent of the impacts would be generally similar in all the alternatives.

Preferred Alternative D2A would result in fewer land use impacts than other Segment D alternatives because construction activities would be located parallel to and north of a new NE 15th/16th Street corridor and within or adjacent to WSDOT and the former BNSF Railway right-of-way, as well as away from other existing land uses. Work along 136th Place NE would have the greatest disruption for adjacent businesses and likely result in right-turn in and out restrictions.

The storage tracks north of NE 12th Street in the former BNSF Railway corridor would result in a minor property conversion of land use to a transportation facility for the small operator’s building and 14 parking stalls and an access easement through an industrial property.

The D2A - NE 24th Design Option would result in additional impacts on adjacent land uses because construction activities would be adjacent to the existing land uses in the Overlake neighborhood.

The extent of the impacts would be greatest under Alternative D3) because of the retained cut required along NE 20th and 152nd Avenue NE, which would limit access to some adjacent commercial land uses. Alternative D5 would result in the lowest extent of land use impacts because most of the alternative would be located in either former BNSF Railway or WSDOT right-of-way and away from surrounding commercial land uses. Alternative D2E would have impacts similar to *Preferred Alternative D2A,* and the extent would be greater than with Alternative D5 and less than with Alternative D3.

Segment E

There would be no additional land use impacts in Segment E other than the common impacts described above; however, the extent of the temporary impacts discussed under Impacts Common to All Build Alternatives would vary depending on the alternative. The Segment E alternatives are primarily located within or adjacent to existing transportation rights-of-way, which would minimize impacts on surrounding land uses.

Preferred Alternative E2 would be primarily located within or adjacent to existing transportation rights-of-way, which would minimize impacts on surrounding land uses. The E2 - Redmond Transit Center Design Option associated with *Preferred Alternative E2* would extend the guideway along 161st Avenue NE to the Redmond Transit Center Station, which would impact adjacent land uses and could affect access.

Alternatives E1 and E4 would result in the most impacts on surrounding residential land uses related to noise, dust, and visual resources because of their proximity to residential areas near West Lake Sammamish Parkway and Leary Way. Alternative E4 would result in greater impacts because of the at-grade construction required along Leary Way, which would result in additional traffic congestion and could affect access to the existing land uses in the area.

4.2.3.4 Maintenance Facilities

Impacts during Operation

Each of the potential facilities would require acquisition and displacement of properties, with MF3 resulting in the greatest number of displacements; MF2 would result in the greatest potential to convert land uses to transportation-related use (23.1 to 23.8 acres), but the fewest number of displacements and acquisitions; and MF1 would result in the greatest number of property acquisitions. The amount of land required for the maintenance facilities would vary based on how the maintenance facilities connect via the alternatives; refer to Chapter 2 for a complete description of the differences between the connections.

Although the Segment D maintenance facilities (MF1, MF2, and MF3) are consistent with the existing land uses, they are not consistent with the new zoning in the Bel-Red neighborhood. The Bel-Red Corridor Final EIS (City of Bellevue, 2007) indicates that new light industrial land uses would no longer be allowed; however, Bellevue would need to accommodate the East Link maintenance facility as an essential public facility if one of these locations were chosen.

Because Bellevue is intending a reduction of industrial uses, there is the potential for indirect impacts on adjacent land uses from the proposed maintenance facility locations in Segment D. MF2 would be located near property zoned for mixed-use, including housing. These land uses might not easily redevelop to include housing from existing industrial uses because of the proximity of the facility. The design of the maintenance facility would incorporate appropriate measures to minimize impacts and help it blend into the surrounding land uses (i.e., the use of a landscape buffer). MF1 would be located adjacent to property zoned for commercial and office-related uses and should not affect development that would occur nearby. MF3 would be located the farthest away from the stations proposed under *Preferred Alternative D2A* and Alternatives D2E and D3 and therefore would have the least impact on the Bel-Red neighborhood redevelopment.

In Segment E, MF5 would be consistent with existing industrial uses, and no impacts on land use patterns would be expected.

Impacts during Construction

Construction impacts would be similar to those described under Impacts Common to All Alternatives; however, because the maintenance facilities proposed are adjacent to light industrial land uses or away from entrances to commercial uses or residential use, the extent of the impact on adjacent land uses would be anticipated to be minor.

4.2.4 Potential Mitigation Measures

No mitigation related to land use would be required during operation of the East Link Project. In general, the East Link Project would not result in inconsistencies with adopted land use plans. Although Sound Transit cannot minimize all disturbances to adjacent land uses during construction, impacts would not be anticipated to cause substantial changes in land use. Therefore, no specific mitigation related to land use would be required. Refer to Section 4.1 for complete information on how Sound Transit would minimize the impacts associated with required acquisitions, displacements, and relocations. Refer to Chapter 3 and Sections 4.3, 4.5, 4.6, 4.7, 4.8, and 4.17 for measures that would minimize impacts on adjacent land uses.

4.3 Economics

4.3.1 Introduction to Resources and Regulatory Requirements

Transit projects like East Link can change patterns of regional and local mobility and access, which in turn might affect aspects of the regional or local economies such as development patterns, employment opportunities, business accessibility, and/or retail sales. Prior to construction, most of the project alternatives would relocate businesses and displace employees. Section 4.1, Acquisitions, Displacements, and Relocations addresses potential relocation of residences and displacement of residents associated with the East Link Project. The East Link Project also might have economic impacts on cities and counties in the area.

The purpose of this economic impacts analysis is to identify the potential adverse and beneficial impacts of the East Link Project on the local and regional economies. Sound Transit evaluated economic impacts in a study area consisting of three different scales:

- **Regional:** Economic impacts on the regional economy (such as effects on employment, traffic mobility, and congestion) were analyzed for a study area consisting of the four counties in the Puget Sound region: King, Kitsap, Pierce, and Snohomish.
- **City level:** Economics impacts of the project on the tax revenue were assessed for cities with property acquisition (Bellevue and Redmond).
- **Site-specific:** Site-specific impacts were evaluated for a study area of 0.5 mile around the light rail route and stations.

This analysis summarizes the anticipated direct and indirect impacts of the No Build Alternative and the East Link Project alternatives from business displacements, changes in tax revenue, and regional transportation of goods and services during operation and construction.

4.3.2 Affected Environment

4.3.2.1 Regional Demographic and Economic Trends

This section provides demographic and economic regional forecasts for the four-county Puget Sound Region.

Population

The historical and forecast population data for the region and for King, Kitsap, Pierce, and Snohomish Counties individually show that by 2030 the region will grow by over 1.2 million inhabitants to 4.5 million inhabitants (see Appendix F4.3, Table F4.3-1). Between 2000 and 2030, population in the region is expected to increase at an average annual growth rate of 1.1 percent. The greatest average annual growth is forecast to occur in Snohomish County, at approximately 1.6 percent, followed by Pierce, Kitsap, and King Counties at 1.2, 1.2, and 0.8 percent, respectively.

Households

The historical and forecast household data for the region and for King, Kitsap, Pierce, and Snohomish Counties individually show that between 2000 and 2030, the number of households in the region is expected to increase at an average annual growth rate of 1.4 percent (see Appendix F4.3, Table F4.3-2). Like the population growth forecast, the most rapid annual rate of household formation, at 1.9 percent, is expected to occur in Snohomish County. Pierce, Kitsap, and King Counties are forecast to have average annual growth rates of 1.5, 1.5, and 1.1 percent, respectively.

Between 2000 and 2030, the growth rate for new household formation is forecast to exceed the growth rate for population in each of the four counties. This implies that the average number of persons per household will decline. This is relevant because travel demand typically correlates more closely to household formation than to population.

Regionally, the mix of households is expected to change between 2000 and 2030, as shown in Appendix F4.3, Table F4.3-2. The percentage of multifamily households is forecast to increase from 31 percent in 2000 to 35 percent in 2030, while the percentage of single-family households is expected to decline from 69 percent in 2000 to 65 percent in 2030. This trend to multifamily households is forecast to occur in all four Puget Sound counties.

Income

Median household income in King, Kitsap, Pierce, and Snohomish Counties is higher than the state average. According to the U.S. Census Bureau, King County had the highest median household income in the region, at approximately $70,193 in 2008, which is an increase of 32 percent from 1999. In 2008, median household income was $59,333 in Kitsap County, $58,217 in Pierce County, and $66,701 in Snohomish County. Nominal income levels in Kitsap, Pierce, and Snohomish Counties have increased by 27, 29, and 26 percent, respectively, when compared with 1999 U.S. Census levels. However, when adjusted for inflation, Kitsap, Pierce, and Snohomish Counties show a slight decrease in income levels between 1999 and 2008. Within King County, there was a slight increase in inflation-adjusted income over the same time period.

Employment

Between 2000 and 2030, employment in the region is expected to grow at an average annual rate of 1.2 percent. Snohomish County is expected to experience the highest rate of increase in job growth, at an average annual rate of 1.6 percent (see Appendix F4.3, Table F4.3-3). Pierce, King, and Kitsap Counties follow with average annual growth rates of 1.1, 1.1, and 1.0 percent, respectively. Snohomish County's relative share of regional employees is forecast to increase from 12 percent in 2000 to 14 percent in 2030, while the relative shares of King, Kitsap, and Pierce Counties are expected to decline slightly.

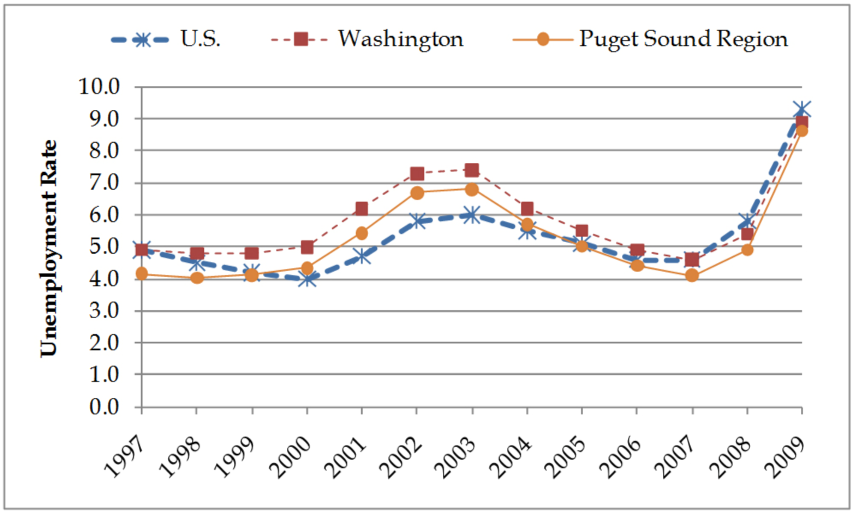

EXHIBIT 4.3-1
Unemployment Rates, 1997 to 2009

Note: Regional unemployment was calculated using an employee-weighted average of the Seattle-Tacoma-Bellevue, Washington, Metropolitan Statistical Area (includes King, Snohomish, and Pierce counties) and the Bremerton-Silverdale, Washington, Metropolitan Statistical Area (includes Kitsap County) annual unemployment rates.

Source: Bureau of Labor Statistics, 2010.

Table F4.3-4 in Appendix F4.3 presents historical and forecast employment by sector, in total, and on a percentage basis, for the region and King, Kitsap, Pierce, and Snohomish Counties. Regionally, the finance, insurance, real estate, and services sector (FIRES) of the economy is forecast to grow the most rapidly. This is also true for King, Pierce, and Snohomish Counties. In Kitsap County, the wholesale trade, transportation services, communication, and utilities sector (WTCU) is forecast to grow most rapidly.

Unemployment

As shown in Exhibit 4.3-1, which charts unemployment rate trends for the region, Washington, and the United States, the region's unemployment rate was lower than that of the state and of the nation from 1997 to 1998. However, between 1999 and 2005, it was higher than the nation but lower than the state. Since 2005, the region's unemployment rate has tended to be lower than the state and the nation. Additionally, since 2000, the unemployment rate within the Cities of Seattle, Bellevue, and Redmond has tended to be lower than that of the Puget Sound region.

4.3.2.2 Demographic and Economic Trends in Study Area

Table 4.3-1 shows the population, household, and employment trends for each segment. The same data for each alternative are available in Appendix F4.3, Table F4.3-5. The tables in Appendix F4.3 provide estimates for 2000 and 2030 forecasts. The estimates for Segment A are based on Seattle Transportation Analysis Zone projections from the City of Seattle; for the remaining segments, the estimates are based on Transportation Analysis Zone projections from the Puget Sound Regional Council (PSRC). As shown in Table 4.3-1, by 2030, Segment C is forecast to have the largest population (52,170) and most households (18,120) and employees (97,540) of the five project segments. Segment C is also forecast to experience the most rapid growth in population, households, and employment, both in total and as a percentage.

The cities within the study area—Seattle, Mercer Island, Bellevue, and Redmond—rely heavily on property tax and sales tax revenues to fund general services to their respective jurisdictions. Revenues collected by each city, other than taxes, consist of funding from state and local sources, internal transfers, and various types of fees collected from government-operated facilities and from issuing licenses and permits. In addition to funding city programs, property tax levies also provide funds for county programs, fire prevention, libraries, schools, and other governmental services.

Table 4.3-2 breaks down funding sources for each city in the study area. Property tax revenues as a percentage of total general fund revenues for the cities range between a low of 9.4 percent for Bellevue and a high of 41.4 percent in Mercer Island. Sales tax revenues, as a percentage of total general fund revenues, range between a low of 10.7 percent in Bellevue to a high of 29.2 percent in Redmond.

TABLE 4.3-1
Population, Household, and Employment Forecasts by Segment

Segment	2000[a]	2030[a]	Average Annual Growth Rate 2000 to 2030 (percent)
Segment A, Interstate 90			
Population	9,240	13,350	1.2
Housing units	3,520	4,930	1.1
Employment	12,550	17,450	1.1
Segment B, South Bellevue			
Population	10,490	13,400	0.8
Housing units	4,110	5,170	0.8
Employment	7,000	9,430	1.0
Segment C, Downtown Bellevue			
Population	15,970	52,170	4.0
Housing units	5,740	18,120	3.9
Employment	51,080	97,540	2.2
Segment D, Bel-Red/Overlake			
Population	16,710	25,170	1.4
Housing units	5,930	8,820	1.3
Employment	64,000	95,310	1.3
Segment E, Downtown Redmond			
Population	19,120	41,780	2.6
Housing units	6,860	14,600	2.6
Employment	23,090	39,900	1.8

[a] Estimates rounded to the nearest 10.

4.3.2.3 Regional Transportation of Goods and Services

In Segment A, I-90 is an important link for regional and interstate commerce. This section describes existing truck trips on I-90 and its current and future importance to the region's economy. A recent study (Sommers, 2003) notes that future growth in the region forecasted by PSRC will be based mainly on the expansion of technology industries and the accompanying expansion of financial and service industries. Long-term growth in King County is projected to be concentrated in the two downtown centers (Seattle and Bellevue) to a much greater extent than in the rest of King County. The growth of the technology sector in Seattle will likely enhance regional economic linkages across Lake Washington to Bellevue and other Eastside communities, where these industries are also well established. The technology and the financial and service industries have a tendency to cluster in downtown areas and dense office parks; they have strong mutual business linkages and tend to locate near each other. These industries will require expansion of both transportation systems and electronic communications infrastructure to carry out their work, suggesting a need for expanded road, transit, and communications capacity between Downtown Bellevue and Downtown Seattle.

Another recent study (Washington State Department of Transportation [WSDOT], 2007) provides insight into how congestion is constraining economic development in the region. Longer travel times, increased costs, and less reliable pick-up and delivery times for truck operators could result in businesses being forced to move all or part of their business to less congested regions or avoid the Puget Sound region altogether. In an effort to avoid moving away from the region, some transport companies are working with their customers to arrange deliveries in nonpeak hours; however, many smaller customers do not find it cost-effective to extend their hours of operation. Congestion also limits access to labor and affects location decisions; as a result, companies might look to less congested parts of the metropolitan region or to other cities entirely for future expansion. The results of a recent Washington State freight movement study (WSDOT, 2005) indicate the following:

- Fourteen billion dollars ($14 billion) in state-originated exports pass through Puget Sound ports, equating to 63 million metric tons of cargo.
- Freight volumes in Washington are growing twice as fast as the state's population and are expected to continue growing rapidly in the future.

- On an average weekday in 2000, congestion in the Puget Sound region resulted in more than 45,000 hours of truck delay.

These results indicate that roadway congestion increases the cost of doing business in the region, particularly for businesses and industries highly dependent on the shipment of goods.

In the Puget Sound region, I-90 is the main highway route for east-west commerce and the secondmost heavily used highway for truck movements in Washington (WSDOT, 2005) after I-5, with over 5,000 truck trips per day, many of which travel over the I-90 bridge en route to the Port of Seattle or other destinations. According to a study of freight movement on Washington state highways (Peterson, et al., 2006), five industries comprise more than half of the freight traffic on I-90: food and related products, crops, lumber and wood products, mixed freight, and transportation equipment. These five industries are particularly vulnerable to delay and unreliable travel times.

PSRC forecasts show that the average annual growth of freight traffic on the I-90 bridge will slow by 2030 during AM and PM peak periods (Table F4.3-6 in Appendix F4.3). (Peak travel time for this analysis is for all vehicles traveling between 7 and 9 a.m. and between 4 and 6 p.m.) This is because, by 2030, traffic congestion on I-90 will be much worse than it is today, and a higher percentage of freight is expected to cross the bridge during off-peak times (peak travel times for freight are generally between the hours of 9 a.m. and 1 p.m.). However, as shown in Appendix F4.3, Table F4.3-6, overall freight movement in the I-90 corridor is still expected to grow annually 1.2 percent in the PM peak hour, which is greater than the region's expected annual population growth rate of 1.1 percent. The overall freight movement in the AM peak hour is expected to grow at a slower pace, 0.3 percent, relative to the region's expected annual population growth.

4.3.3 Environmental Impacts

A new light rail system like East Link can cause changes in the local business environment and surrounding neighborhoods. These changes, in turn, might change the success of existing businesses and influence future economic opportunity in the area. Direct economic impacts of each alternative could include business and employee displacements and the corresponding potential tax impacts, potential changes in development patterns and regional freight mobility, and potential impacts on businesses and property near the routes and stations. Indirect impacts could result from proximity impacts, including changes in parking availability, noise, visual effects, and access. This section evaluates these impacts for each alternative and station.

4.3.3.1 No Build Alternative

The No Build Alternative consists primarily of funded or committed roadway and transit actions by the state and by regional and local agencies; these include other projects that are considered likely to be implemented. Under the No Build Alternative, future economic development or redevelopment would not likely be the same as it would be with the East Link Project. Under the No Build Alternative, planned land use changes in the Bel-Red and Overlake neighborhoods could occur more slowly or might not reach the full density permitted under the zoning regulation. Congestion also would likely worsen and there would be fewer alternatives to single-occupancy vehicle travel, which could impact future economic development.

4.3.3.2 Direct Impacts during Operation

The following subsections discuss direct impacts related to displacing businesses and employees and initial impacts on the local tax base for each alternative and maintenance facility.

Displacements

Table 4.3-3 provides estimates of the number of businesses located at properties that would be partially or fully acquired by the East Link Project alternatives and lists the estimated number of employees at those businesses. The estimates were prepared based on field verification of business names and information included in Section 4.1, Acquisitions, Displacements, and Relocations. PSRC employment data and square foot per employee estimates (Pflum, et al., 2004) were used to estimate the number of employees displaced within each alternative, based on the type of business: civic and quasipublic, commercial, industrial, office, and retail.

To provide a perspective on the relative magnitude of the business displacement impact, Table 4.3-4 compares the number of employees estimated to be displaced with the total forecast average annual growth in employment in each segment. Total employment estimates are not available at the alternative level; therefore, segment-level data were used. As shown for the high employee displacement estimates, in all segments except Segment C, the project would displace more jobs than are added annually in a typical year; however, for the low estimates, the project would displace fewer jobs than are added annually in a typical year.

TABLE 4.3-3
Property Acquisition Impacts on Businesses and Employees

Alternative		Full Displacements		Commercial, Public, and Institutional Property Acquisitions	
		Business	Employees	Partial	Full
Segment A, Interstate 90					
Preferred Interstate 90 Alternative (A1)		0	0	0	0
Segment B, South Bellevue					
Preferred 112th SE Modified Alternative (B2M)	To *Preferred Alternative C11A*	0	0	11	1
	To *Preferred Alternative C9T*	0	0	11	1
Bellevue Way Alternative (B1)		2	10	17	3
112th NE At-Grade Alternative (B2A)		0	0	10	1
112th NE Elevated Alternative (B2E)		0	0	8	1
112th SE Bypass Alternative (B3)		0	0	9	1
B3 – 114th Extension Design Option		14	170	12	2
BNSF Alternative (B7)		6	160	8	6
Segment C, Downtown Bellevue					
Preferred 108th NE At-Grade Alternative (C11A)[a]		39 (39 to 40)	330 (330 to 380)	24 (24 to 27)	19 (19 to 20)
Preferred 110th NE Tunnel Alternative (C9T)[a, b]		17 to 18	160 (160 to 300)	14 (14 to 16)	10 (10 to 11)
Bellevue Way Tunnel Alternative (C1T)		21	250	24	11
106th NE Tunnel Alternative (C2T)		13 to 20	170 to 240	15 to 17	7 to 14
108th NE Tunnel Alternative (C3T)		15 to 22	180 to 270	8 to 11	10 to 17
Couplet Alternative (C4A)		36 to 37	490 to 550	15 to 16	19 to 21
112th NE Elevated Alternative (C7E)		29 to 30	670 to 730	11 to 12	3
110th NE Elevated Alternative (C8E)		33	750	12	9
110th NE At-Grade Alternative (C9A)		17 to 18	170 to 230	10 to 11	10 to 11
114th NE Elevated Alternative (C14E)		24	390	13	10
Segment D, Bel-Red/Overlake					
Preferred NE 16th At-Grade Alternative (D2A)[c]		34	550	40	8
D2A - NE 24th Design Option		69	1,060	49	13
NE 16th Elevated Alternative (D2E)		42	920	25 to 27	16
NE 20th Alternative (D3)		74	1,590	77 to 79	17
SR 520 Alternative (D5)		79	480	29 to 31	2
Segment E, Downtown Redmond					
Preferred Marymoor Alternative (E2)		8	290	8	7
E2 - Redmond Transit Center Design Option		23	350	18	11
Redmond Way Alternative (E1)		7	210	13	5
Leary Way Alternative (E4)		7	120	12	3

TABLE 4.3-3 CONTINUED

Property Acquisition Impacts on Businesses and Employees

Alternative	Full Displacements		Commercial, Public, and Institutional Property Acquisitions	
	Business	Employees	Partial	Full
Maintenance Facilities				
116th Maintenance Facility (MF1)				
Preferred NE16th At-Grade (D2A), NE 16th Elevated (D2E), and NE 20th (D3) Alternatives	77	890	5	15
SR 520 Alternative (D5)	82	630	4	17
BNSF Maintenance Facility (MF2)				
Preferred NE16th At-Grade (D2A), NE 16th Elevated (D2E), and NE 20th (D3) Alternatives	5	450	5	3
SR 520 Alternative (D5)	6	850	1	5
SR 520 Maintenance Facility (MF3)				
Preferred NE16th At-Grade (D2A) and NE 16th Elevated (D2E) Alternatives	60	890	4	9
NE 20th Alternative (D3)	56	840	7	8
SR 520 Alternative (D5)	57	870	0	9
SE Redmond Maintenance Facility (MF5)				
Redmond Way Alternative (E1)	38	410	3	13
Preferred Marymoor Alternative (E2)	16	310	4	7
Leary Way Alternative (E4)	16	310	1	7

Note: Estimates rounded to the nearest 10.

[a] The value before the parentheses indicates impacts associated when the alternative connects to *Preferred Alternative B2M*. The value in parentheses indicates range of impacts associated with the Segment C preferred alternative connections to Segment B alternatives, including *Preferred Alternative B2M*.

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M.*

[c] Impacts associated with D2A - 120th Station Design Option are the same as for the *Preferred Alternative D2A*.

TABLE 4.3-4
Comparison of Annual Average Employment Growth and Total Employees Displaced by Segment

Segment	Employment		Average Annual Growth		Employment Displacements (Total)	
	2000	2030	Percent	New Jobs	Low	High
A, Interstate 90	No business displacements					
B, South Bellevue	7,002	9,431	1.0	70	20	170
C, Downtown Bellevue	51,079	97,330	2.2	1,110	160	750
D, Bel-Red/Overlake	63,996	97,264	1.4	899	475	1,590
E, Downtown Redmond	23,087	37,016	1.6	366	250	350

Note: Excludes displacements from maintenance facilities.

Source: Employment forecasts from PSRC (2006); employment displacements from Table 4.3-3.

More jobs would be added in Segment C annually than would be displaced by the project. Table 4.3-3 also shows the alternatives for which there would be many employees displaced with few property acquisitions. The number of employees displaced would be approximately 2 percent or less of total employment for all segments.

The number of affected employees does not necessarily mean jobs that would be lost, because Sound Transit would provide relocation assistance to displaced businesses. Therefore, it is likely that many of the displaced jobs would be relocated and not lost. However, some displaced businesses and jobs, particularly industrial businesses in the Bel-Red Corridor, would probably relocate outside the City of Bellevue because of the land use and zoning changes planned for that area.

Segment A
As shown in Table 4.3-3, Sound Transit would not acquire any private property for *Preferred Interstate 90 Alternative (A1)*; therefore, no businesses or employees associated with *Preferred Alternative A1* would be displaced.

Segment B
Neither of the *Preferred 112th SE Modified Alternative (B2M)* variations (i.e., connection to *Preferred C11A* or *Preferred C9T*) would displace any businesses or employees. However, the *Preferred Alternative B2M* would displace 1 residence and partially acquire up to 11 properties; these partial acquisitions would not displace any businesses or employees.

The impacts to employees and businesses associated with many of the other Segment B alternatives are similar to the impacts of *Preferred Alternative B2M*. The 112th SE At-Grade (B2A), 112th SE Elevated (B2E), and 112th SE Bypass (B3) Alternatives would not displace any businesses or employees. The B3 – 114th Design Option would acquire 14 businesses and displace 170 employees, the most businesses and highest number of employee displacements of any Segment B alternative. The businesses displaced would be associated with acquiring a parcel containing office buildings in the Bellefield Office Park; these displacements would only occur if the B3 - 114th Design Option were implemented. The BNSF Alternative (B7) would acquire 6 businesses and displace 160 employees, the second most employees displaced of any Segment B alternative.

Segment C
Preferred 108th NE At-Grade Alternative (C11A) would displace 39 businesses and 330 employees, which is fewer than many of the other alternatives within Segment C. *Preferred 110th NE Tunnel Alternative (C9T)* would displace 17 to 18 businesses and between 160 and 330 employees, which is similar to the other Segment C tunnel alternatives (Bellevue Way Tunnel [C1T], 106th NE Tunnel [C2T], and 108th NE Tunnel [C3T] Alternatives).

Business displacements that would occur with the other Segment C alternatives would range between a low of 13 associated with Alternative C2T and a high of 37 associated with Couplet Alternative (C4A). The displaced employees associated with other Segment C alternatives range between a low of 170 associated with Alternatives C2T or C9A and a high of 750 associated with 110th NE Elevated Alternative (C8E).

Segment D
Preferred NE 16th At-Grade Alternative (D2A) would displace about 34 businesses and about 550 employees, which is higher than SR 520 Alternative (D5) but lower than all other Segment D alternatives. D2A - 120th Station Design Option would have impacts on businesses and employees that would be similar to *Preferred Alternative D2A;* D2A - NE 24th Design Option would displace about 69 businesses and about 1,060 employees, the second highest number of employee displacement of all Segment D alternatives.

Business displacements related to other Segment D alternatives would range between a low of about 42 associated with NE 16th Elevated Alternative (D2E) and a high of 79 associated with Alternative D5. Displaced employees associated with property acquisition for other Segment D alternatives range between a low of 480 associated with Alternative D5 and a high of 1,590 with NE 20th Alternative (D3).

Segment E
Preferred Marymoor Alternative (E2) would displace about 8 businesses and about 290 employees, which would be similar to the other Segment E alternatives. However, the E2 - Redmond Transit Center Design Option would have the highest overall impact on businesses (23) and employees (350) of any Segment E alternative. The City of Redmond has plans to locate a stormwater pipe and trail within the former BNSF railway, in downtown Redmond, which would reduce the amount of space available for the light rail. This constraint may require that light rail be shifted to accommodate the stormwater pipe and trail, which may require the partial acquisition of properties on the north side of the railway to accommodate all proposed facilities as well as the train. If the alignment is shifted north, it would have no impact on businesses in this area. The two other Segment E alternatives (Redmond Way [E1] and Leary Way [E4] Alternatives) would

each displace about 7 businesses, each alternative would displace 210 and 120 employees, respectively.

Maintenance Facilities
The 116th Maintenance Facility (MF1), with access from Alternative D5, would have the most full property acquisitions: it would relocate 82 businesses and 630 employees from 10 properties. The SR 520 Maintenance Facility (MF3), with access from *Preferred Alternative D2A* and Alternative D2E, would result in the highest overall impact on employees (890) of any of the maintenance facilities.

The SE Redmond Maintenance Facility (MF5), along *Preferred Alternative E2* and Alternative E4, would displace the fewest number of employees (385 employees from 16 businesses located on 7 properties). Although these employees would be displaced through these property acquisitions, Sound Transit estimates that 115 to 144 new jobs, including operators and maintenance staff, would be created at the maintenance facility. As noted above, the number of affected employees does not necessarily mean jobs that would be lost because Sound Transit would provide relocation assistance to displaced businesses. Thus, it is likely that many of the displaced jobs would be relocated, not lost.

Impacts of Displacements on Tax Base of Cities

In each alternative other than *Preferred Alternative A1*, Sound Transit would acquire residential and commercial properties. Table 4.3-5 presents the 2010 initial property tax impacts on cities resulting from property acquisitions and includes potential impacts from full acquisitions. The property tax impacts are annual estimates based on 2010 levy rates and 2009 assessed values. The City of Bellevue would be affected by alternatives in Segments B, C, and D, and the City of Redmond would be affected by alternatives in Segments D and E. When referring to the property tax impacts of acquisitions, the term "initial property tax impacts" is used because the extent of the long-term fiscal impact of the system is uncertain. Initially, property taxes would no longer be collected from full acquisitions along the route. As a result, the rates charged to remaining taxpayers could increase slightly to recover budgeted funds, or budgets for essential government services could be reduced accordingly.

In the long run, some of the excess land purchased by Sound Transit for system construction likely would be released for development once the project is built; this is particularly likely for the staging areas in Segment C. Between 23 percent and 45 percent of the property tax impacts in Segment C would result from purchasing land for staging areas that would likely become available for redevelopment after the project is built. Further, some displaced businesses are likely to rebuild at a new location elsewhere within the jurisdiction's boundary. In addition, the East Link Project might serve as a catalyst for future private development and investment. Thus, the East Link Project's long-term property tax impacts would likely be less, potentially zero, or even beneficial once existing businesses are reestablished, staging areas are released for development, and new development consistent with this project occurs. For example, new development is expected to occur in Segment D where both Bellevue and Redmond have adopted new land use plans to increase density and promote mixed use development. These positive fiscal impacts could be offset somewhat by the absence of new construction that might have occurred on properties acquired and retained by Sound Transit. Thus, the long-term property tax impacts are uncertain but are highly likely to be less than the initial property tax impacts.

Segment A
As shown in Table 4.3-5, Sound Transit would not acquire any private property for Segment A; therefore, there would not be any initial property tax impacts associated with *Preferred Alternative A1*.

Segment B
For both variations of the *Preferred Alternative B2M*, Sound Transit would acquire one residential property, which is located on Mercer Slough Blueberry Farms lot (publicly owned land) and exempt from property taxes.

Sound Transit would acquire private properties for other alternatives within Segment B, which would result in property tax impacts. The B3 - 114th Extension Design Option and Alternative B7 would have the greatest property tax impact of any Segment B alternative, resulting in initial impacts of $17,500 and $14,500, respectively. However, these impacts are relatively small (about 0.03 percent) when compared with the 2010 estimated property tax revenues for the City of Bellevue.

Segment C
Preferred Alternative C11A would fully acquire about 28 private properties and result in an initial property tax impact to the City of Bellevue of about $68,500 (0.10 percent of total city property tax revenues). *Preferred Alternative C9T* would fully acquire about 18 private properties and would result in an initial property tax of about $45,000 (0.07 percent of total city property tax revenues). If the optional station at Main Street for *Preferred Alternative C9T* were selected, it would not have any additional impacts and may add benefit to nearby businesses.

TABLE 4.3-5
Initial Property Tax Impacts on Cities by Alternative

Alternative	Annual Initial Property Tax Impact		Percent of Budgeted City 2009-2010 Property Tax Revenues	
	Low	**High**	**Low**	**High**
Segment A, Interstate 90				
Preferred Interstate 90 Alternative (A1)	0		0.00	
Segment B, South Bellevue				
Preferred 112th SE Modified Alternative (B2M) (connecting to *C11A* or *C9T*)	0		0.00	
Bellevue Way Alternative (B1)	$7,000		0.01	
112th SE At-Grade Alternative (B2A)	$1,500		Less than 0.01	
112th SE Elevated Alternative (B2E)	$500		Less than 0.01	
112th SE Bypass Alternative (B3)	$1,500		Less than 0.01	
B3 – 114th Extension Design Option	$17,500		0.03	
BNSF Alternative (B7)	$15,500		0.02	
Segment C, Downtown Bellevue				
Preferred 108th NE At-Grade Alternative (C11A)	$68,500		0.10	
Preferred 110th NE Tunnel Alternative (C9T)[b]	$45,000		0.07	
Bellevue Way Tunnel Alternative (C1T)	$88,500		0.13	
106th NE Tunnel Alternative (C2T)	$33,000	$53,000	0.05	0.08
108th NE Tunnel Alternative (C3T)	$33,500	$53,500	0.05	0.08
Couplet Alternative (C4A)	$56,000	$71,500	0.08	0.11
112th NE Elevated Alternative (C7E)	$41,000	$56,000	0.06	0.08
110th NE Elevated Alternative (C8E)	$95,000		0.14	
110th Avenue NE At-Grade Alternative (C9A)	$22,000	$37,000	0.03	0.06
114th Avenue NE Elevated Alternative (C14E)	$40,000		0.06	
Segment D, Bel-Red/Overlake				
Preferred NE 16th At-Grade Alternative (D2A) [a]	$45,500 to $60,500		0.06 to 0.09	
D2A - 120th Station Design Option	$60,500		0.09	
D2A - NE 24th Design Option	$45,500	$60,500	0.06	0.09
NE 16th Elevated Alternative (D2E) [a]	$71,500		0.08	
NE 20th Alternative (D3)	$64,500		0.10	
SR 520 Alternative (D5)	$8,500		0.01	
Segment E, Downtown Redmond				
Preferred Marymoor Alternative (E2)	$32,500		0.12	
E2 - Redmond Transit Center Station	$75,500		0.27	
Redmond Way Alternative (E1)	$22,500		0.08	
Leary Way Alternative (E4)	$13,000		0.05	

TABLE 4.3-5 CONTINUED
Initial Property Tax Impacts on Cities by Alternative

Alternative	Annual Initial Property Tax Impact		Percent of Budgeted City 2009-2010 Property Tax Revenues	
	Low	High	Low	High
Maintenance Facilities				
116th Maintenance Facility (MF1)	$53,000 to $56,000		0.08	
BNSF Maintenance Facility (MF2)	$31,500 to $58,000		0.05 to 0.09	
SR 520 Maintenance Facility (MF3)	$42,500 to $49,500		0.06 to 0.07	
SE Redmond Maintenance Facility (MF5)	$37,000 to $54,000		0.13 to 0.19	

[a] Includes both impacts to Cities of Bellevue and Redmond.

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M.*

Source: King County Department of Assessments, 2010; City of Bellevue, 2010; City of Redmond, 2010.

The other Segment C alternatives would result in a range of property tax impacts between a low of $22,000 associated with Alternative C9A and a high of $95,000 associated with Alternative C8E. The range of impact to the City's 2010 estimated property tax revenues would be between 0.03 percent and 0.14 percent.

Segment D

Preferred Alternative D2A would fully acquire about eight private properties and result in an initial property tax of about $45,500 (0.07 percent). The D2A - NE 24th Design Option would fully acquire an additional five properties and result in an initial property tax impact of about $60,500. Many Segment D alternatives would result in full acquisitions and property tax impacts to both the City of Bellevue and Redmond; however, the properties acquired for *Preferred Alternative D2A* would only impact the City of Bellevue (the D2A – NE 24th Design Option would impact both jurisdictions).

The other Segment D alternatives would result in a range of property tax impacts between a low of $8,500 associated with Alternative D5 and a high of $71,500 associated with the Alternative D2E. Of the $71,500, about $60,000 would impact the City of Bellevue's 2010 property tax revenue and about $11,500 would impact the City of Redmond's 2010 property tax revenue.

Segment E

Preferred Alternative E2 would fully acquire about nine private properties and result in an initial property tax of about $32,500 (0.12 percent). This impact would be relatively higher than most other Segment E alternatives. But the E2 - Redmond Transit Center Design Option would result in the highest overall property tax impact with a $75,000 annual impact, which would account for 0.27 percent of 2009-2010 city revenues.

The other Segment E alternatives would result in a range of property tax impacts between a low of $13,000 associated with Alternative E4 and a high of $22,500 associated with the Alternative E1. Similar to property tax impacts, the long-run tax impacts from other taxes are uncertain. There might be some lost sales taxes or revenue from other taxes and fees if displaced businesses do not relocate within the same city. These types of losses would be offset to the extent that existing businesses relocate and business activity increases and/or new businesses are attracted to the area. Local jurisdictions are likely to receive some sales tax revenues from purchases related to project construction.

Impacts on Regional Transportation of Goods and Services

This section discusses the project impacts project on the regional transportation of goods and services. The main impacts would result from changes in freight mobility on the I-90 bridge.

Compared with the No Build Alternative, the East Link Project is expected to allow greater total 2030 peak-period freight volumes on I-90 across Lake Washington and improved overall 2030 peak-period travel times. However, most trucks do not use I-90 during peak hours, and the travel time during off-peak hours would remain unaffected. Improved truck travel times during peak periods would lower the cost of shipping goods and services across I-90. Thus, the proposed project is expected to benefit regional freight mobility, with associated benefits for the regional economy. Support for this conclusion is presented in Table 4.3-6 where PM peak-period travel times (volume-weighted) between 4 and 6 p.m. are expected to be on average 5 minutes faster under the project by 2030. The AM peak-period travel times (volume-weighted) between 7 and 9 a.m. are expected to remain relatively unchanged, on average. Volume-weighted travel times during the sum of the AM and PM peak periods are expected to average approximately 3 minutes faster than under the No Build Alternative. The lower forecasted travel times are mainly because there would be fewer commuters on I-90 with the project because many of them are expected to use light rail as an alternative transportation mode. Chapter 3 Transportation Environment and Consequences fully describes I-90 transportation impacts.

Volume-weighted travel time

Volume-weighted travel time considers the number of trucks traveling at one time in each direction during the peak period. As an example, if there are seven trucks westbound that take 10 minutes each and five trucks eastbound that take 8 minutes each, the volume-weighted travel time would be 9.2 minutes (7x10 + 5x8)/12.

4.3.3.3 Indirect Impacts during Operation

The evaluation of the potential for indirect economic impacts of the alternatives is based on field observations of each alternative, on the number of housing units and employees to be served by the stations (see Table F4.3-5 in Appendix F4.3), and on information presented in Chapter 3, Transportation Environment and Consequences.; Section 4.2, Land Use; Section 4.5, Visual and Aesthetic Resources; and Section 4.7, Noise and Vibration.

Both positive and negative indirect economic impacts can result from East Link Project operation. Positive indirect economic effects from light rail projects can result in increased development and redevelopment potential adjacent to stations. Negative indirect economic effects on business are disturbances that might change access, traffic flow, business sales, or value of adjacent property. Local negative indirect effects include access restrictions, decreased parking availability, noise, and visual impacts on land uses. The following subsections analyze these impacts.

Positive Indirect Impacts

The availability of light rail increases transit access and pedestrian activity, especially in areas surrounding the stations and between important nodes of economic activity. Improved transit access can improve the convenience, visibility, and desirability of surrounding residential and commercial properties. Increased pedestrian activity can increase the patronage of adjacent retail uses. This might result in the synergy of business and employee interest in locating where there is convenient access to the light rail line, leading to more dense land uses around stations and, therefore, resulting in increased economic activity at stations. This pattern is referred to as transit-oriented development (TOD) and is addressed further in the Section 4.2, Land Use. The economic impacts are summarized here.

TABLE 4.3-6
Current and Forecast 2-Hour Peak-Period Freight Truck Volumes and Travel Times across the I-90 Bridge

		Base Year		2030 No Build [a]		2030 No Build [b]		2030 Build

[d] Travel times are between I-405 and I-5 (Seattle).

Recent studies indicate that residential and commercial property values near light rail transit stations typically increase and are valued higher than similar properties that are not near the transit stations. In Denver, for instance, a recent market analysis of the apartment market conducted by Grubb & Ellis indicated that people are willing to pay approximately 4 percent more per month to rent an apartment within a 0.25 radius of a light rail station. The analysis also found that, from 2006 to 2010, developers have paid an average of 25 percent more for unimproved apartment land within a 0.25 radius of an existing or planned transit stop (Jackson, 2010) In Buffalo, a 2007 study suggested that homes within a quarter-mile radius of a light rail station typically have an increased property value of 2 to 5 percent of the city's median home value (Hess and Almeida, 2007). Additional studies have suggested similar trends in cities across the country, including Washington D.C., San Francisco, Portland, and various other cities (Parsons Brinckerhoff, 2001).

It should be noted that these payoffs are not automatic, and property-value increases generally require a strong demand for real estate, locations in neighborhoods free from signs of stagnation and distress, and public policies such as zoning bonuses that further leverage TOD and transit system expansion that produces the spillover benefits of a highly integrated transportation network. Property values are also affected by external forces and might change in response to fluctuations in the economy, consumer confidence, and local development pressures. In addition, because TOD takes time to evolve, property value benefits will also take time to accrue (TRB, 2004). While this effect is likely to occur in all segments, the benefits might be most realized in Segment D, where both Bellevue and Redmond have adopted supportive plans for TOD and market conditions appear strong. Each alternative in Segment D except the SR 520 Alternative (D5) is anticipated to cause positive indirect impacts on adjacent economic activity. The length of Alternative D5 adjacent to SR 520 includes fewer stations near planned intensification of land uses; this might cause Alternative D5 to have a smaller positive indirect impact on adjacent economic activity.

Negative Indirect Impacts

As described in the previous section, studies have found property value impacts from light rail transit to be usually positive. However, there are also other studies that have documented decreased property values for properties located near transit stations. A 2009 study in Atlanta, based on an analysis of properties near five stations, suggests that proximity to transit had minimal impact on property values there (Lambert, 2009). Moreover, in the area surrounding Atlanta's only station in a true TOD setting, property values actually increased as the distance from the station increased. In addition, the 2007 Buffalo study found that—despite positive proximity affects overall—low-income station areas actually had negative proximity effects. In other words, in low-income areas, property values decreased as proximity to stations increased. Proximity to a light rail route, rather than a station, might also result in decreased property values (TRB, 2004). Disruptive noise levels; light, shadow, and view impacts; and reductions in vehicle access and parking can affect property values and sales for businesses that depend on vehicular access. Negative impacts on property values are most likely to occur when the light rail project results in noise or visual impacts noticeably greater than what currently exists. These impacts are more often associated with elevated, and to a lesser degree, at-grade alternatives, and are generally negligible for tunnel alternatives. Most of the East Link alternatives are at-grade or elevated.

As with potential positive indirect impacts, potential negative indirect impacts are by no means a guarantee. The same external forces described above—real-estate demand, local zoning, and economic climate, for example—can combine in different ways to result in either positive or negative indirect impacts.

Section 4.5, Visual and Aesthetic Resources, and Section 4.7, Noise and Vibration, suggest that there is relatively little potential for these impacts to be of a sufficient magnitude to result in negative property value impacts. The visual quality analysis (Section 4.5) indicates that residential properties in some alternatives would experience impacts on currently high-quality views, resulting in a permanent change in visual quality. This impact would not occur under *Preferred Alternative B2M* but would occur under the following other alternatives: Alternatives B1, B2A, B2E, B3, C9A, and E4. Of these alternatives, Alternative B2E would have the most potential for impacts. Those impacts may occur at a few residential properties, located along Bellevue Way between the park-and-ride lot and the intersection with 112th Avenue SE, having views that would be directly affected. However, for all of these alternatives, there would be no sensitive views blocked, no solar access impacts, and no light and glare impacts. With the Alternative C14E, if tent structures are used for the elevated Bellevue Transit Center Station and the pedestrian bridge, then views of the Cascade Mountains might be blocked from some locations on NE 6th Street and 110th Avenue NE (such as the City Hall Plaza, the Meydenbauer Conference Center, and the existing Bellevue Transit Center). However, this impact would not affect any residential viewers, and these structures would not be out of scale or character with existing urban development in the general area.

Noise and vibration impacts on residential and commercial properties would potentially occur in a number of alternatives. Noise impacts would be mitigated (see Section 4.7 Noise and Vibration), thus reducing substantially the likelihood that noise or vibration would contribute to negative property value effects. Some residual vibration impacts would occur that may not be mitigated in the following alternatives:

- One commercial location each for Alternatives C8E, C9A, and C14E when connecting to the Alternative B3 or B7 in Segment B
- One multifamily residential location for Alternative C8E
- Two multifamily locations for Alternative C4A
- Two multifamily locations for Alternative C9A
- One single-family residence each for *Preferred Alternative E2*, Alternative E1, and E2 - Redmond Transit Center Design Option

Displaced off-street parking due to partial property acquisitions might reduce business opportunities. The value of displaced parking depends on the quantity of spaces lost and the business type.

Segment A

There would be no negative indirect vehicle access or off-street parking impacts associated with *Preferred Alternative A1*.

Segment B

For *Preferred Alternative B2M*, business access would be maintained at intersections and major ingresses and egresses. When *Preferred Alternative B2M* connects to *Preferred Alternative C9T,* the east approach at SE 15th Street to the Bellefield Office Park would close.

Alternative B1 would reduce drivers' ability to make left-hand turns in the median, affecting some businesses. This change and reduced parking would have a minimal impact on the operation of these businesses. Impacts from the other Segment B alternatives would be similar to the impacts discussed for *Preferred Alternative B2M* above (i.e., business access would be maintained at intersections and major ingress and egresses).

Segment C

There would likely be no adverse economic impacts related to access, off-street customer parking or traffic circulation associated with *Preferred Alternative C11A*. *Preferred Alternative C11A* would remove on-street parking and limit left-turn access to some office complexes and retail businesses. This could potentially economically impact the retail businesses that profit from convenient on-street parking. However, the affected streets are dominated by high-rise buildings that contain underground parking; therefore, this impact would be limited to few businesses. Some of this adverse impact would be offset by improved visibility of some businesses by transit riders.

There would not likely be adverse economic impacts related to access, off-street customer parking, or traffic circulation associated with the *Preferred Alternative C9T*.

Most other Segment C alternatives are grade-separated—tunneled or elevated—with the exceptions of Alternatives C4A and C9A and some short, retained-cut portions of Alternative C1T. These alternatives would not likely result in adverse economic impacts related to access, off-street customer parking, or traffic circulation. Alternatives C4A and C9A would remove on-street parking and limit left-turn access to some office complexes and retail businesses. This could potentially result in similar limited indirect economic impacts to those described under *Preferred Alternative C11A* above.

Segment D

Preferred Alternative D2A would reduce off-street parking and restrict left-turn access due to the at-grade route associated with it. These conflicts could cause some adverse economic impact. However, these conflicts are not located along business frontages except for fairly short distances, because only a short portion of the NE 16th Street corridor currently exists. Indirect economic impacts associated with D2A - 120th Station Design Option would be the same as without this design option. D2A - NE 24th Design Option would result in the same indirect economic impacts as *Preferred Alternative D2A* but would also include access restrictions along NE 24th Street and 152nd Avenue NE.

Similar to the *Preferred Alternative D2A*, portions of Alternatives D2E andD3 would reduce the number of off-street parking stalls and restrict left-turn access. For Alternative D3, the restaurants and retail businesses along NE 20th Street would experience a greater impact relative the impacts cited for the *Preferred Alternative D2A*. In Segment D, the Alternative D5 would have the least adverse economic impact when compared to the other alternatives in Segment D.

Segment E

Preferred Marymoor Alternative (E2) would not be likely to result in adverse economic impacts during operation because most of the alternative is either adjacent to SR 520 or along the former BNSF Railway corridor. However, some restaurants and retail businesses along 161st Avenue NE would experience reduced left-turn access which could result in reduced economic activity for these businesses. Similar to the reasons cited above for the *Preferred Alternative E2*, the other Segment E alternatives would not likely result in adverse economic impacts during operation.

4.3.3.4 Impacts During Construction

This section considers the positive and negative economic impacts that might occur during project construction. Construction brings money into the economy with construction jobs, purchasing of local goods and services for construction, and the money spent by construction crews in the community where construction occurs. On the negative side, constructing any alternative could result in economic impacts by blocking visibility and access to businesses, causing traffic delays, and rerouting traffic on detours that increase travel times and make access to some locations difficult.

Potential Positive Economic Impacts from Construction

Constructing any alternative would result in increased employment and spending in the project vicinity during construction. The extent of these impacts depends on the source of project funding and the makeup of work crews used during project construction.

In economic impact analysis, typically only inflows of funds from outside a region are considered "new money" that will lead to new employment and income in that region. Funds from local or regional sources are transfers that could be spent by residents and businesses on other economic activities. Excepting an estimated $93 million of federal grant funds, the funds required for project construction are anticipated to be raised in the communities benefiting from the project (Sound Transit, 2007a), which seems to imply that there would be relatively little "new money" available for spin-off economic benefits to the region. However, project construction would lead to positive economic effects beyond just the federal grants. Sound Transit would issue bonds to pay for project construction, and this money would go primarily to businesses located within the region within a relatively short period of time. Principal and interest on the bonds would be repaid over many years using a variety of funding mechanisms. Some of the future repayments are likely to be made in the form of taxes on visitors to the region, which represent additional inflows of funds to the region. Thus, there would be a temporal impact because bonded funds would be spent over approximately 8 years stimulating direct and indirect construction spending in the region. This would be offset in the long run by a negative impact on economic activity from added taxes to pay for the project, but some of the negative impact would be offset by taxes on visitors to the region.

Quantifying the economic impacts from project construction is complex, but some indication of the magnitude of the economic stimulus that would result from the project's preferred alternative is shown in Table 4.3-7. This table provides an estimate range of the direct expenditures and the proportion of project employment that would be hired from the three-county region as a result of the low- or high-cost projects. The table also provides ranges within the high and low cost estimates to reflect the two variations in how *Preferred Alternative B2M* connects to Segment C. As shown, the high-cost estimate of the preferred alternative would result in approximately $1.86 billion to $2.00 billion of spending in the region, and 1,925 to 2,075 direct jobs per year in the region over an assumed 8-year period for project design and construction. The low-cost estimate of the preferred alternative would result in approximately $1.61 billion to $1.74 billion of spending in the region and approximately 1,670 to 1,800 direct jobs per year in the region during the 8-year period for project design and construction. In addition to these direct effects, additional indirect benefits would occur when the output of firms in other industries increases to supply the demand for inputs to the construction industry. Wages paid to workers in construction trades or supporting industries would be spent on other goods and services; these are referred to as induced impacts. Direct, indirect, and induced impacts would occur in the region from project construction. The indirect and induced impacts are often called "multiplier" impacts. Multiplier estimates for the three-county region (Minnesota Implan Group, Inc. 2007) suggest that an additional 46 percent of value added (i.e., payments made by industry to workers, interest, profits, and indirect business taxes) would result from new direct construction spending in the region, and an additional 1.56 new jobs would be created for every direct job associated with the project, increasing the potential number of jobs generated in the region to approximately 34,150 to 42,500.

TABLE 4.3-7
Direct Expenditures and Direct Employment in Three-County Region from East Link Construction of Preferred Alternative

	Project Construction	Right-of-Way	Total
High-Cost Estimate			
Direct Expenditures			
Total direct expenditures (million 2007 $)[a]	$2,850 to $3,073	$149 to $161	**$2,999 to $3,234**
Percent in three-county region[b]	60	100	**N/A**
Three-county direct expenditures (million 2007 $)	$1,710 to $1,844	$149 to $161	**$1,859 to $2,004**
Direct Employment			
Total direct employment[b]	21,039 to 22,685	669 to 721	**21,708 to 23,406**
Percent in three-county region[b]	70	100	**N/A**
Three-county direct employment	14,728 to 15,880	669 to 721	**15,396 to 16,601**
Annual direct employment	1,841 to 1,985	84 to 90	**1,925 to 2,075**
Low-Cost Estimate			
Direct Expenditures			
Total direct expenditures (million 2007 $)[a]	$2,471 to $2,665	$129 to $139	**$2,600 to $2,804**
Percent in three-county region[b]	60	100	
Three-county direct expenditures (million 2007 $)	$1,483 to $1,599	$129 to $139	**$1,612 to $1,738**
Direct Employment			
Total direct employment[b]	18,244 to 19,675	580 to 625	**18,823 to 20,300**
Percent in three-county region[b]	70	100	**N/A**
Three-county direct employment	12,770 to 13,772	580 to 625	**13,350 to 14,397**

[b] Sound Transit, 2007b.

Although the typical methodology for economic impact analysis would count only the $93 million of federal grant funding as new spending for the purposes of determining economic impacts, the actual benefits would be greater and are difficult to determine precisely. Regardless of the specific method used to quantify economic impacts, it is clear that the project would result in substantial short-term economic activity in the region during construction.

Potential Negative Economic Impacts from Construction

The following subsections document the types of activities that could potentially occur during the various phases of construction and their relative impacts on local businesses within each segment. Construction activity can result in impacts on local businesses because of the associated changes in traffic circulation, access, parking, noise, and visual effects. Along any given area of the project, civil construction is anticipated to last approximately 3 to 5 years.

Segment A

In Segment A, *Preferred Alternative A1* would use existing right-of-way with an at-grade trackway throughout the segment. Temporary construction along 5th and 23rd Avenues South in Seattle would affect circulation with minimal impact on parking garages, office, or retail businesses. This would not likely result in a substantial adverse economic impact. No short-term construction impacts are expected on Mercer Island because local traffic circulation would not substantially change in the short term.

Segment B

In Segment B, *Preferred Alternative B2M* would be constructed on the east side of Bellevue Way and either on the east side or in the median of 112th Avenue SE, depending on whether it connects to *Preferred Alternative C11A* or *C9T*. This would avoid roadway reconstruction except where necessary to accommodate additional traffic turn lanes and to restore areas disrupted by construction activities. Project construction would temporarily relocate the Mercer Slough Blueberry Farm sales office and the

Winters House activities within Bellevue, but it would not result in long-term closure of these enterprises. The Eastside Heritage Center is a nonprofit organization and a tenant of the Winters House, which is owned by the City of Bellevue. Alternative B1 runs completely at-grade along Bellevue Way. The other Segment B alternatives, except for Alternatives B1 and B7, run along Bellevue Way and 112th Avenue SE and would substantially reconstruct these roadways. This construction activity would cause temporary detours and lane closures, which would increase congestion on Bellevue Way and 112th Avenue SE. Most businesses along each alternative are professional offices that do not rely heavily on drive-by traffic to attract customers; however, along Alternative B1, there are a few retail businesses that would be likely to suffer adverse impacts during construction. These construction-related impacts would not occur with Alternative B7, as this alternative avoids Bellevue Way and 112th Avenue SE and travels east parallel to I-90, then north along the former BNSF Railway corridor parallel to I-405. Construction at 118th Station could result in minor traffic delays for businesses located south on 118th Avenue SE, but these business do not rely on pass-by traffic.

Segment C

Preferred Alternative C11A would partially close roads along 112th Avenue SE, Main Street, 108th Avenue NE, and NE 6th Street. This would result in reduced accessibility, construction-related noise, and dust during site preparation and construction. Businesses in this area are primarily large office buildings with support services such as restaurants and cafes. Few retail businesses that depend on drive-by traffic are located in this area of downtown.

Preferred Alternative C9T would require a cut-and-cover tunnel, affecting businesses along 110th Avenue NE between Main and NE 6th Streets; however, traffic access would be maintained to the extent possible. Construction noise would be experienced during site preparation and construction.

Alternatives that require cut-and-cover tunnel construction would result in the most substantial adverse economic impacts on local businesses because this construction method requires relatively deep excavation of streets and typically results in access restrictions to businesses near the construction until covers can be installed over the construction area. Alternatives C1T and C2T would require the largest amount of cut-and-cover tunnel construction along Bellevue Way and NE 6th Street and along commercial areas of Main Street, 106th Avenue NE, and NE 6th Street, respectively. Bored tunnels would also have impacts, although they would be smaller than the cut-and-cover alternatives. Because it is mostly a bored tunnel, Alternative C3T could likely have fewer adverse business impacts because surface disruptions on traffic, utilities, and buildings would be minimized during boring; however, construction would result in high noise impacts, truck congestion, and traffic lane closures at tunnel access portals. Types of businesses located along the three tunnel alternatives include offices, retail, and restaurants. Those businesses that rely on drive-by traffic to attract customers would be adversely affected.

Along elevated routes in Segment C, most businesses along each alternative are professional offices that do not rely heavily on drive-by traffic to attract customers; however, there are a few retail businesses that may be adversely affected during construction. For Alternative C8E, there are a number of retail and restaurant businesses between NE 2nd and NE 12th Streets, and these businesses would likely experience more pronounced impacts than would be expected for businesses along the elevated sections of the other alternatives. Businesses along the at-grade portion of Alternative C4A would experience a shorter construction period with fewer disruptions; therefore, impacts on these businesses would likely be less severe than those of any other section of the alternatives. Constructing Alternative C14E along 114th Avenue NE would reduce this road to one lane of traffic between Main Street and NE 6th Street, but business and emergency access would be maintained. Construction noise impacts on local businesses would occur during the site preparation and project construction. At-grade construction activities for Alternative C9A would include detour routes, short-term and long-term lane closures, and loss of on street parking.

Segment D

Construction impacts associated with *Preferred Alternative D2A* would include short-term and long-term lane closures and the loss of on-street parking. Construction activities would close the Overlake Transit Center to construct the light rail station, transit loop, and multilevel parking garage. Under D2A - NE 24th Design Option, lane closures would temporarily affect businesses along portions of NE 24th Street and 152nd Avenue NE. Noise, vibration, vegetation removal, dust, loss of parking, construction traffic, and lane closures would temporarily affect businesses along portions of NE 16th Street and 136th Place NE for *Preferred Alternative D2A*. The D2A - NE 24th Design Option would add NE 24th Street and 152nd Avenue NE to the list of affected roadways.

The preferred storage track within the former BNSF Railway corridor might require temporary easements through business parking lots, but it is not anticipated to impede access or reduce business activities for adjacent businesses.

Similar to *Preferred Alternative D2A*, the other alternatives within Segment D would cause temporary detours and lane closures, but for relatively short periods of time, except for Alternative D3. Alternative D3 would travel in the median of NE 20th Street, both at-grade and retained cut, causing longer impacts on more businesses than any of the other Segment D alternatives, including *Preferred Alternative D2A*. The businesses that would most likely experience a decline in sales during construction are those that rely heavily on drive-by traffic to attract customers, such as fast food restaurants and other retail businesses. Alternative D2E would have impacts similar to those of *Preferred Alternative D2A*, but these impacts would more heavily affect the south side of NE 24th Street, as opposed to the north side with *Preferred Alternative D2A*. All access on NE 24th Street to the Overlake Shopping Center would be closed during construction, possibly resulting in additional economic impacts on these businesses relative to the other Segment D alternatives. Alternative D2E would also cause additional disruption as it turns to the north across NE 24th Street to run along 152nd Avenue NE. Alternative D5 would be constructed adjacent to SR 520 and behind retail businesses; therefore, the impacts on access, parking, and circulation would probably be minor.

Segment E
Preferred Alternative E2 might require temporarily closing some roadway crossings of the former BNSF Railway corridor during station and track construction. Construction noise would occur during the site preparation and project construction. Although there would not likely be any substantial impacts on businesses, because there are roadways on either side of the former BNSF Railway corridor that provide a buffer to adjacent business and preserve accessibility during construction, there might be minor dust, noise, and congestion impacts along side streets. Under E2 - Redmond Transit Center Design Option, construction along 161st Avenue NE could remove several businesses, as well as cause effects from noise, dust, and congestion. Businesses could also experience reduced access and parking during construction.

From the Overlake Transit Center to the West Lake Sammamish Parkway NE interchanges, alternatives in Segment E travel between businesses and SR 520 but would not affect access or parking. However, there might be minor dust, noise, and congestion impacts along side streets. The construction impacts for other Segment E alternatives would be similar to the impacts cited for the *Preferred Alternative E2,* above. Elevated portions of the alternatives over the West Lake Sammamish Parkway NE interchange might result in night closures of SR 520 or short-term detours without causing an adverse impact on traffic. Construction equipment might affect parking and business activity for businesses north of SR 520 for the Alternatives E1 and E4.

Maintenance Facilities
Each maintenance facility is located within existing industrial areas of Segments D and E that support a number of warehousing, industrial, and transportation facilities, except for the SR 520 Maintenance Facility (MF3), which is located on a mix of retail and industrial property north of Northup Way. Businesses in the area require good vehicular, truck, and/or rail freight access. The levels of business and transportation activity, and the likely adverse construction economic impacts, would be greatest for maintenance facilities in Segment D because they are located along already congested streets. The SE Redmond Maintenance Facility (MF5) would probably have the lowest traffic-related construction economic impacts of the four sites because of the presence of fewer nonindustrial businesses and transportation facilities.

4.3.4 Potential Mitigation Measures

Adverse impacts are more likely to occur for businesses near surface construction activities. The cut-and-cover tunnels and stations in Segment C would likely have the greatest impact on nearby businesses in terms of noise, dust, and restricted access. Noise and vibration mitigation is provided in Section 4.7, Noise and Vibration, and mitigation for displaced businesses is discussed in Section 4.1, Acquisition, Relocations, and Displacements. As described in Section 4.3.3.4, construction might cause adverse impacts on businesses due to reduced access or general construction activity. Transportation mitigation is provided in Chapter 3, Transportation Environment and Consequences.

To minimize or limit impacts, Sound Transit would dedicate staff to work specifically with affected businesses during construction to minimize the associated impacts. Construction mitigation plans would be developed to address the needs of businesses and could include, but are not limited to, the following elements:

- Provide a 24-hour construction telephone hotline.
- Provide business cleaning services on a case by case basis.
- Provide detour, open for business, and other signage as appropriate.
- Establish effective communications with the public through measures such as meetings and construction updates, alerts, and schedules.
- Implement promotion and marketing measures to help affected business districts maintain their customer base, to the extent possible, during construction.
- Maintain access as much as possible to each business and coordinate with businesses during times of limited access.
- Provide a community ombudsman.

Please refer to the arterials and local streets construction mitigation measures in Section 3.6.5 of Chapter 3 for additional measures that would help mitigate economics impacts.

4.4 Social Impacts, Community Facilities, and Neighborhoods

4.4.1 Introduction to Resources and Regulatory Requirements

This section evaluates how the East Link Project might affect communities and neighborhoods in the area. Consistent with guidance from the Federal Transit Administration (FTA) and Federal Highway Administration (FHWA), four key neighborhood and community issues are considered when addressing the affected environment and potential impacts of a transportation project: changes in neighborhood quality, barriers to social interaction, impacts on community resources, and impacts on safety and security. The analysis also considers demographics of potentially affected areas.

The study area for social impacts, community facilities, and neighborhoods consists of a 0.5-mile radius from the centerline of alternatives, with emphasis around the stations. Neighborhoods adjacent to the stations are more likely to be directly and indirectly influenced, positively and negatively, by project construction and operation. Much of the impact analysis for this section overlaps with issues evaluated in other sections, so the following sections may be consulted where appropriate:

- Section 4.2, Land Use, describes land uses and zoning in the study area.
- Section 4.3, Economics, details population, housing, and impacts on property values.
- Section 4.6, Air Quality, describes local and regional air quality.
- Section 4.7, Noise and Vibration, describes potential noise and vibration impacts.
- Section 4.14, Public Services, details information on fire, emergency medical, police, schools, and postal services (locations of public services are shown in exhibits in this Section 4.4).
- Section 4.17, Parkland and Open Space, describes the study area recreational resources.
- Chapter 3, Transportation Environment and Consequences, describes impacts on regional and local traffic, transit, and nonmotorized transportation.
- Appendix C, Environmental Justice, describes impacts on minority and low-income populations.

4.4.2 Affected Environment

The East Link Project would connect to Central Link at the International/Chinatown Station in Seattle and provide light rail service to the Eastside communities via Interstate 90 (I-90). The East Link alternatives pass through Seattle, Mercer Island, Bellevue, and Redmond. This section describes neighborhood characteristics, including location, development pattern, demographics, community resources, economic characteristics, safety and security, and accessibility. Neighborhoods located within the study area are identified by segment in Exhibits 4.4-1 to 4.4-6. The exhibits also identity the locations of community facilities, including parks, schools, religious institutions, social services, and public service facilities. A general description of neighborhoods by segment follows.

The demographic makeup of populations in areas within 0.5 mile of the stations for each project alternative is shown in Table 4.4-1. These estimates are based on a geographic information system (GIS) extraction of 2000 Census data for the Census Blocks and Census Block Groups within each station area. The population data for residents living within the station areas were then aggregated to create a demographic profile of the total population that would be affected by the project. The demographic information in the table includes information on the total population within 0.5 mile and the percentage of the total population that is minority, low-income, senior citizens, or households with no vehicle who reside within 0.5 mile of the stations. Based upon the information in the table, Segment A includes the highest percentage of minority, low-income, and households with no vehicle that would have access to the stations, and the stations in Segment C contain the highest percentage of senior citizens within 0.5 mile of the stations.

4.4.2.1 Segment A, Interstate 90

The study area for Segment A includes portions of four City of Seattle neighborhoods and Mercer Island. I-90 is a barrier between the neighborhoods in Seattle and bisects Mercer Island. However, the lids and the public recreation facilities over the freeway provide connections in both cities allowing residents to interact and travel easily across I-90 at several locations. The prominent north-south arterials include Airport Way South, Rainier Avenue South, 23rd Avenue South, and Martin Luther King, Jr. Way in Seattle, and Island Crest Way on Mercer Island.

E2 - Redmond Transit Center Design Option		9,824	26.5	8.2	7.4	5.5
Redmond Way Alternative (E1)/Leary Way Alternative (E4) [g]		8,637	28.0	9.3	8.3	5.98

Source: U.S. Census, 2000.

[a] Being of African, Hispanic, Asian- American, American Indian or Alaskan descent.

[b] Those with a median household income that is at or below the U.S. Department of Health and Human Services poverty guideline as defined by U.S. Department of Transportation Order 5610.2, § Appendix 1(b)

[c] Each alternative has the same population shown.

[d] C9T – East Main Station Design Option connecting from *Preferred Alternative B2M* would eliminate the Segment B SE 8th Station; therefore, the demographics are the same as *Preferred Alternative B2M* to *Preferred Alternative C11A.*

[e] B3 – 114th Extension Design Option impacts would be the same as those for Alternative B3.

[f] C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

[g] Population totals are for those census block groups and census blocks with more than 90 percent of the census area within the station radius; overlapping station radii have been clustered by alternative to capture the whole urban cluster and avoid double counts.

[h] Population data are based on the 2000 Census Block population.

[i] D2A – 120th Station Design Option impacts would be the same as those for *Preferred Alternative D2A*.

The International District was the original home of Seattle's Chinese residents and is now the heart of the Asian community. Other focal points in the International District include the Uwajimaya Shopping Center, Union Station, and religious facilities. Land uses adjacent to the alternative within this neighborhood include a mixture of commercial and offices, many unique to the Asian cultures present there.

The Duwamish and Pioneer Square neighborhoods contain regional activity centers of Qwest Field and Events Center, King Street Station, and Safeco Field. The residential areas along Segment A within Seattle are older medium-density neighborhoods with a mixture of mostly single-family and some multifamily housing, although the International District contains some pockets of high-density housing.

Public recreation facilities in the Central Area and North Rainer Valley neighborhoods include Judkins Park and Playfield, Sam Smith Park, and the Mountains-to-Sound Greenway Trail (I-90 Trail), which parallels I-90. The primary commercial area in these neighborhoods is adjacent to Rainier Avenue and 23rd Avenue South. The newly opened Northwest African American Museum (see Exhibit 4.4-1) is located in the historic Colman School, located at South Massachusetts Street and 23rd Avenue South. The building also contains 36 units of mixed-income rental housing managed by the Housing Resources Group.

Segment A travels through Mercer Island, and the Mercer Island Station would be located adjacent to the Town Center Neighborhood (see Exhibit 4.4-2). The Town Center is the commercial core of Mercer Island and includes a mixture of commercial, office, and multifamily residential uses.

Recent mixed-use developments within the 76-acre Town Center have led to greater densities and a more walkable community. Low-density, single-family residential subdivisions surround the Town Center. Community facilities within the study area include public recreation facilities located to the south, the Mountains-to-Sound Greenway Trail (I-90 Trail) to the north, the Community Center at Mercer View, and Ellsworth House senior housing. Access from I-90 is provided at Island Crest Way, 77th Avenue, West Mercer Way, and East Mercer Way. Island Crest Way is the main arterial traveling to the south end of the island from I-90.

4.4.2.2 Segment B, South Bellevue

The Segment B study area includes portions of eight City of Bellevue neighborhoods (see Exhibit 4.4-3). The alternatives follow existing local roadways and transportation infrastructure (Bellevue Way SE, 112th Avenue SE, former BNSF Railway corridor, and I-405), which currently act as boundaries between the study area neighborhoods. The Segment B study area also contains the highly used South Bellevue Park-and-Ride on Bellevue Way SE (520 parking stalls) and the Wilburton Park-and-Ride (186 parking stalls), located at the I-405/SE 8th Street interchange.

The Enatai, Killarney Circle, and Southwest Bellevue neighborhoods are bounded to the east by Bellevue Way SE. These neighborhoods primarily comprise well-established suburban, single-family residences. Community resources include Enatai Elementary School, and Southwest Bellevue's churches serve the residents of the immediate area as well as the larger community. Religious and community events provide many opportunities for residents to come together. The South of Downtown Residential Neighborhood is bounded between Bellevue Way SE and 112th Avenue SE and encompasses the Surrey Downs and Bellecrest neighborhoods. North of the Bellevue Way SE and 112th Avenue SE intersection, land uses consist of a mixture of commercial and retail to the east, and some multifamily, and to the west it is single family transitioning to multifamily.

There are established neighborhood businesses along Bellevue Way SE, which provide a sense of place and continuity for residents in a fast-changing city. Identified by the community as unique businesses (Exhibit 4.4-3), Chace's Pancake Corral, Triangle Swim Club, the Mercer Slough Blueberry Farm, the Chevron Station, and the Bellevue Nursery are located close to these neighborhoods and are among the businesses that have for many years contributed to the unique quality of life of Bellevue residents.

The Mercer Slough residential and commercial neighborhoods are linear neighborhoods located along I-405. The Mercer Slough residential neighborhood consists of a mixture of multifamily residences and office buildings. The only community facility is the Environmental Education Center at Mercer Slough Nature Park. The Mercer Slough commercial neighborhood is located between 112th Avenue SE and I-405 and is composed of commercial buildings, office buildings, and three hotels. The Wilburton Park-and-Ride is also located within the neighborhood. The Mercer Slough Nature Park is located between Bellevue Way SE and the Mercer Slough residential neighborhood, and Winters House and Mercer Slough Blueberry Farm are located within the park (refer to Section 4.17, Parkland and Open Space, for a description of the park and its facilities).

The Woodridge and Wilburton neighborhoods are located east of I-405, separated from the study area by the freeway.

4.4.2.3 Segment C, Downtown Bellevue

The Segment C study area is located primarily within the Downtown Bellevue neighborhood, with outlying sections located in or adjacent to it, including the South of Downtown Residential, Northtowne, Wilburton, and Bel-Red Corridor neighborhoods (see Exhibit 4.4-4). For the most part, the alternatives follow the existing roadway grid between SE 6th Street and NE 12th Street. The Bellevue Transit Center straddles NE 6th Street between 108th and 110th Avenues NE.

Within the South of Downtown Residential neighborhood is the Surrey Downs neighborhood, which consists of primarily single-family residential homes. There are some small businesses located adjacent to Main Street in the northern portion of the neighborhood. Community facilities include Bellevue High School, King County District Court, and Surrey Downs Park located on the site of the Surrey Downs Elementary School, which closed in 1981.

As the name implies, the Downtown Bellevue neighborhood forms the core of Bellevue. Downtown Bellevue, once a suburban business district, is now a large urban center with nearly 6,500 residents and a regional employment center with nearly 45,000 workers (BDA, 2010). Downtown Bellevue includes the regional commercial centers of Bellevue Square, Lincoln Square, and The Shops at Bravern. The new residences in the Downtown Bellevue neighborhood are primarily condominiums and apartments. Land uses in the neighborhood include a mixture of commercial, office, and multifamily residences located in a number of high-rise towers. The area around the Bellevue Transit Center provides transit-oriented development (TOD) with higher densities of residential, commercial, and office development close to the transit center. This area is highly urban with large city blocks, but due to the mixed uses, the neighborhood is walkable. Community facilities within the neighborhood include the Bellevue First Congregational Church, Bradford Center, Meydenbauer Center (events and exhibition facility), the Bellevue Regional Library, the Bellevue Arts Museum, and Bellevue City Hall.

The Northtowne neighborhood consists primarily of single-family residences. McCormick Park is located within this neighborhood and provides a buffer between Northtowne and Downtown Bellevue. Although Downtown Bellevue includes several north-south arterials, only Bellevue Way SE, 108th Avenue NE, and 112th Avenue NE provide access through downtown and into the Northtowne neighborhood. There are no other community facilities located nearby.

The Wilburton and Bel-Red Corridor neighborhoods are located east of I-405. Land uses within the Wilburton neighborhood in this area are primarily auto-oriented commercial, with a number of auto dealerships located along 116th Avenue NE, and also include retail and commercial uses. The Bel-Red Corridor neighborhood within the study area comprises mainly medical-related office buildings and the Overlake Hospital and Group Health Medical Centers. No community facilities are located within these portions of the neighborhoods.

4.4.2.4 Segment D, Bel-Red/Overlake

The Segment D study area includes the Bel-Red Corridor and is generally bounded between SR 520 to the north and Bel-Red Road to the south. SR 520 acts as a barrier between the Bridle Trails neighborhood and the light rail project alternatives. Aside from SR 520, major east-west arterials include NE 20th Street and Bel-Red Road.

The focal area of Segment D is the Bel-Red Corridor in Bellevue, which is predominantly industrial and commercial establishments, and the Overlake Village in Redmond, which consists of commercial retail establishments, hospital services, and senior housing and office parks (see Exhibit 4.4-5). The Bel-Red Corridor in this area is primarily commercial and industrial land uses, including a King County Metro bus base and distribution facilities. The Overlake neighborhood contains a mix of multifamily and single-family housing. The Microsoft campus in Overlake is a major employment center for the region. The Overlake Transit Center serves the Microsoft office campuses as well as the adjacent neighborhood communities.

As discussed in Section 4.2, Land Use, the Bel-Red and Overlake areas have adopted changes in the future land use that would support light rail. These changes also include TOD, which would cause an increase in the overall density and change the character of the neighborhood through mixed-use development of commercial, office, and residential uses.

4.4.2.5 Segment E, Downtown Redmond

The Segment E study area is primarily along SR 520 and ends in the Downtown Redmond neighborhood (see Exhibit 4.4-6). SR 520 is the only freeway to and from Redmond, and it connects to major roadways that serve communities beyond Redmond, including

West Lake Sammamish Parkway NE, SR 202, Redmond Way, and Avondale Road. Otherwise, the Downtown Redmond grid street pattern is interrupted by the former BNSF Railway corridor that runs diagonally through the town center. Redmond Transit Center is located at 161st Avenue NE and NE 83rd Street near the Redmond City Hall.

Neighborhoods within the study area include SE Redmond and Downtown Redmond as well as a large portion of Marymoor Park (Exhibit 4.4-6). The Downtown Redmond neighborhood developed around the former BNSF Railway train station and track, which bisects the town into northern and southern commercial areas. Downtown Redmond includes a mixture of medium-density, multifamily housing and retail uses and a civic center that includes Redmond City Hall, Redmond Library, and the Redmond Police Department. For surrounding communities, downtown is a shopping destination and includes the Redmond Town Center, a mixed-use facility that includes a regional shopping center, a hotel, and office buildings. Other draws to Downtown Redmond include Marymoor Park and open spaces, trails, and the Redmond Saturday Market, an open air market that operates from May to October. The Southeast Redmond neighborhood contains both low-density single-family residential development and a corridor of retail and light industrial commercial uses along SR 202. One regional activity center in Segment E is Marymoor Park, a large regional public recreation and events facility owned and operated by King County.

Located north of Downtown Redmond, the Education Hill and Bear Creek neighborhoods consist primarily of single-family residences. On a bluff west of Downtown Redmond there is an area of primarily multifamily residential units that is part of the Grass Lawn neighborhood. A small portion of the Sammamish Valley is also located within the study area and consists of mostly business parks, with no community facilities located within the study area.

4.4.2.6 Maintenance Facility Surroundings

In Segment D, the maintenance facilities (116th [MF1], BNSF [MF2], and SR 520 [MF3]) are located in the Bel-Red Subarea neighborhood of Bellevue. In Segment E, the SE Redmond Maintenance Facility (MF5) is located within the SE Redmond neighborhood. Sections 4.4.2.4 and 4.4.2 provide information on these neighborhoods.

4.4.3 Environmental Impacts

The analysis of potential impacts of the East Link Project on neighborhoods considers the following key neighborhood and community issues: changes in neighborhood quality, barriers to social interaction, impacts on community resources, and impacts on public services, safety, and security. Much of the impacts evaluation in this section is based on analyses conducted for other sections of this Final EIS, including Chapter 3, Transportation Environment and Consequences; 4.1, Acquisitions, Displacements, and Relocations; 4.2, Land Use; 4.3, Economics; 4.5, Visual and Aesthetic Resources; 4.6, Air Quality and Greenhouse Gases; 4.7, Noise and Vibration; 4.14, Public Services; and 4.17, Parkland and Open Spaces. Impacts from these resources do not automatically constitute an adverse social impact or impact on neighborhood cohesion. Rather, these impacts are evaluated collectively with mitigation measures for their impact on community facilities and neighborhoods. Cohesion is defined as the extent to which residents have a sense of belonging to their neighborhood and considers the interactions between the residents and the resources located in that neighborhood.

Appendix C, Environmental Justice, addresses impacts to minority and low-income populations. Overall, the project would not result in disproportionately high and adverse impacts on minority and low-income populations, but it would provide substantial benefits that would positively affect minority and low-income populations in the areas surrounding the light rail stations. These benefits include improved access to transit; a safer, more reliable, and more efficient transportation system; improved mobility through the project vicinity; transit travel time savings; improved accessibility to employment; and extended transit service hours.

4.4.3.1 No Build Alternative

The No Build Alternative would avoid the property acquisitions and other related changes associated with light rail construction and operation. Those who reside in or travel to and from neighborhoods in the study area would not be provided with a reliable mode of transportation and increased transit accessibility. There would be no change to neighborhood quality.

4.4.3.2 Impacts during Operation

This section addresses the impacts, both positive and negative, that would affect neighborhoods as a whole and is followed by a segment-by-segment analysis of the impacts that would occur within each segment and project alternative.

Neighborhood Quality

A new transportation mode operating on a fixed-rail system has the potential to affect neighborhood quality. Federal guidance states that neighborhood quality impact analysis should be a "qualitative discussion of [the] cumulative impact of" the following factors: property acquisitions and land use changes (including consistency of new development with existing neighborhoods), visual or physical intrusion of the new facility on traffic and parking, and noise and vibration.

In general, neighborhoods served by light rail stations would benefit both from increased transit access and from potential development within station areas in a manner consistent with neighborhood land use goals and plans. Neighborhoods (particularly those portions near station areas) might experience increased vitality in terms of improved access, residential infill, growth in employment base, and greater patronage of local businesses. Goals for regional, local, and station area planning emphasize reducing reliance on automobiles and providing increased pedestrian access and pedestrian-oriented design.

The East Link Project would result in impacts on a number of properties located along neighborhood boundaries. Those nearby might be affected by the changes due to the East Link Project. However, the overall neighborhood quality would not change because the project alternatives travel along existing arterials, which in many instances already act as boundaries for the neighborhoods.

Property Acquisitions and Land Use Changes

Overall, the property acquisitions required for each segment represents a small portion of the land available in adjacent neighborhoods and would not result in changes in the existing neighborhood's intactness or character. Aside from Segment A, all of the alternatives would acquire and displace residential and commercial properties. Although the project would acquire residential dwellings in the neighborhoods, none of the displacements would result in the neighborhoods being bisected or separated from other portions of the neighborhood. Property acquisition impacts would not adversely affect neighborhood quality because the project is primarily located along the edge of the neighborhoods and either on or adjacent to existing roads, which does not create barriers.

Under many alternatives, several businesses might be displaced. Most commercial properties that would be displaced by the East Link alternatives do not provide unique services to the surrounding neighborhoods (i.e., corner store, cafe, coffee shop) and tend to be either office complexes or light industrial uses that are likely to draw employees from the surrounding region. Because most of the commercial properties are not unique to the surrounding neighborhoods, the impacts on the neighborhood character and quality would be minimal.

Some of the properties that would be acquired could be redeveloped consistent with existing zoning after construction. Also, TOD consisting of higher density residential and mixed-use development, typically around the proposed stations, could potentially result as an indirect impact (see Section 4.2, Land Use). These redevelopment opportunities would only occur where allowed by comprehensive and neighborhood plans and where stations can support TOD. For those areas that are primarily single-family residential development, TOD is not allowed under current zoning. TOD allows for creating compact, walkable communities that provide increased transit ridership and reduced traffic congestion and driving. Section 4.2 gives information on potential TOD and identifies those areas where redevelopment would be encouraged and those areas where it would not be encouraged. Redevelopment near stations could enhance economic activity by expanding neighborhood business districts. Section 4.3, Economics, give additional information on the economic benefits from redevelopment near stations.

Visual or Physical Intrusion

Visual changes would be noticeable from some residences located adjacent to or with views of the East Link Project, especially in areas where the alternatives would be elevated above the existing transportation infrastructure or where vegetation would be removed. When possible, vegetation removed for the project would be replaced and landscaping would be provided to screen sensitive visual environments and/or sensitive viewers where necessary, which would minimize the visual impacts. While the East Link Project would introduce another form of transportation, the project would be located primarily within heavily developed urban areas and the alternatives would be located along major transportation facilities where light rail is generally compatible (e.g., local roads, freeway infrastructure, powerlines, tall buildings), so the impacts related to visual quality would generally not adversely affect neighborhood quality for the entire neighborhood. Section 4.5, Visual and Aesthetic Resources, provides complete information on the visual impacts associated with the East Link Project.

Transportation and Parking

Overall, impacts on property access and circulation would be generally limited to the loss of some midblock, left-hand turn movements and turning restrictions of right-in/right-out for alternatives in the roadway's median. Some travelers might be affected by the loss of left turns and the need to travel a more circuitous route. For alternatives that are at-grade or elevated, U-turns would be provided at signalized intersections to minimize the impact on traffic circulation. The Couplet Alternative (C4A) would convert 108th and 110th Avenues NE from two-way streets to a one-way couplet, which would change circulation patterns. Elevated sections would cause minimal access issues because access could be maintained under the guideway.

Traffic impacts that would result from the East Link Project can be mitigated. Park-and-ride lots associated with the stations would be expected to attract more traffic and could impact traffic operations more than if the project were not constructed. In addition, because the alternatives are mostly located within or adjacent to existing arterials, the traffic impacts on the surrounding neighborhoods are expected to be minimal.

Neighborhoods could be affected as a result of light rail riders parking in neighborhoods adjacent to stations. The potential exists for hide-and-ride (when transit users park in neighborhoods surrounding the transit stations), and the best ways to mitigate the impact are unique to each station and the surrounding areas (see Chapter 3 for more information). In neighborhoods where parking does not currently have restrictions, Sound Transit would work with the applicable jurisdictions to implement prevention strategies (i.e., time limits or neighborhood permit programs) in order to maintain neighborhood quality.

The East Link Project would provide a reliable mode of transportation and result in improved transit accessibility and connections for riders between the study area neighborhoods and community facilities within 0.5 mile of the stations, as well as provide connections to regional destinations (i.e., Seattle-Tacoma International Airport and the University of Washington). Overall, the project would improve transit travel times, reliability, and convenience. No alternatives would have negative impacts on pedestrian and bicyclist movements (see Chapter 3 for more information).

Noise and Vibration

The number and severity of noise impacts would vary along each segment and alternative. Where alternatives are at-grade and the roadway must be widened to accommodate the light rail system, traffic noise impacts could increase. However, after noise mitigation has been introduced (e.g., sound walls, special trackwork, and/or building insulation), no adverse noise-related impacts would occur, and noise would not negatively affect the overall neighborhood quality for the entire neighborhood. In addition, there are locations within Segments C and E where vibration impacts might not be mitigated to levels below FTA criteria. Sound Transit would refine analysis of these locations during final design to further minimize or eliminate the impacts. Section 4.7, Noise and Vibration, provides information on potential noise and vibration impacts and potential mitigation measures.

Social Interaction

None of the project alternatives would create new barriers to interaction because they travel along existing arterials that already act as a barrier along the fringe of existing neighborhoods. Stations on these arterials could enhance the cohesion as new meeting points for adjoining neighborhoods. Where portions of the project would be at-grade, crossing points would be maintained at existing signalized intersections to allow continued access within and between communities. Where tunnel alternatives are proposed, there would be no impacts on community cohesion because the trains would be located beneath the neighborhood. In addition, the East Link Project could improve cohesion with increased transit access and TOD, which might indirectly enhance the walking experience and safety of the neighborhoods.

Community Resources

The East Link Project is not expected to result in long-term operation impacts on the civic community resources (e.g., parks, churches, and schools) located within the study area, except for a few park resources where portions of the resource would be permanently impacted, as described in Section 4.17, Parkland and Open Space. These impacts would primarily be felt by those close to the facilities and would not result in permanent adverse impacts on the surrounding neighborhoods.

Safety and Security

Maintaining safety and security at the stations, park-and-ride lots, and the neighborhoods surrounding these facilities is another important consideration for many residents within surrounding neighborhoods. As described in Section 4.14, Public Services, incidences of crime are most likely to occur at the stations; however, crime is not expected to increase as a result of operation of the stations. Typically, crime around stations mirrors crime rates in the surrounding neighborhoods. In the areas around all but one of the proposed stations (Rainier Station), crime is low compared to the surrounding jurisdictions of King County and Washington. Sound Transit would employ security personnel, but also as a matter of practice, Sound Transit implements Crime Prevention through Environmental Design (CPTED) principles directed at reducing crime incidents at stations and park-and-ride lots. Other measures to minimize crime would include using equipment (i.e., closed circuit TV, sealed fareboxes, and automatically sealed exits), using anticrime programs such as antigraffiti programs, and using security personnel. Because these design elements would be integrated throughout the East Link Project, there would not be the potential for project-related safety and security impacts in adjacent neighborhoods.

Segment A

Overall, operating *Preferred Interstate 90 Alternative (A1)* in Segment A would have little impact on neighborhoods because it is located in the center lanes of I-90 and would be similar in character to the areas through which it would pass. There would be no displacements nor land use changes that would affect neighborhood quality. The two proposed stations (Rainier and Mercer Island) would be consistent with the visual character of the areas where they are located and would not reduce visual quality. Noise from light rail operations is not expected to cause a change in the overall noise levels in the adjacent neighborhoods because I-90 would continue to be the dominant noise source. The station would provide enhanced accessibility to Mercer Island neighborhoods. Because *Preferred Alternative A1* travels primarily within existing Washington State Department of Transportation (WSDOT) I-90 right-of-way, no new barriers would be created that would affect community cohesion or access between community resources, and public services. *Preferred Alternative A1* would not negatively affect neighborhoods in Seattle or Mercer Island.

Segment B

The Segment B alternatives follow existing local roadways and transportation infrastructure (Bellevue Way SE, 112th Avenue SE, and former BNSF Railway corridor), which currently act as boundaries along the fringe of adjacent study area neighborhoods (see Exhibit 4.4-3). None of the alternatives would travel through existing neighborhoods but rather would travel along the edges of neighborhoods along existing arterials. The Segment B alternatives would acquire some property acquisitions, displace some residences and businesses, result in some minor changes in property access, remove vegetation, and add new structures; these impacts can negatively affect nearby residents and businesses. These impacts are not expected to markedly alter the overall land use or development character of the neighborhoods located within Segment B because the neighborhoods are well defined, with roadways such as Bellevue Way SE and/or 112th Avenue SE serving as an existing boundary. Therefore, the project is not expected to interrupt neighborhood social interactions. Although there would be impacts associated with the East Link Project, the overall neighborhood quality in the affected study area would not likely change.
Table 4.4-2 summarizes the factors used to assess impacts on neighborhoods by alternative. In addition to assessing how the project might change neighborhood quality, the following discusses possible changes to social interaction, community resources, and safety.

Along Bellevue Way SE, *Preferred 112th SE Modified Alternative (B2M)* is located farther east and, therefore, farther away from the Enatai neighborhood than other Segment B alternatives that travel along Bellevue Way SE and would not affect neighborhood quality. There would be fewer visual impacts because *Preferred Alternative B2M* transitions to a retained cut after leaving the South Bellevue Station. However, constructing the retained cut would remove vegetation from the intersection at 112th Avenue SE and Bellevue Way, which would be a visual change until the new plantings and remaining vegetation mature. *Preferred Alternative B2M* would result in the highest permanent park impacts on the Mercer Slough Nature Park; however, the alternative would not substantially affect park use, features, activities, and attributes, and existing park community resources would be maintained. *Preferred Alternative B2M* would not add new barriers to social interaction.

For *Preferred Alternative B2M* to *C11A*, the landscaped median along 112th Avenue SE would be removed, and the light rail elements would be more visible than with the connection to *C9T*. *Preferred Alternative B2M* to *C9T* would remain east of 112th Avenue SE connecting to the SE 8th Station, which would enhance neighborhood access to transit. If the C9T – East Main Station Design Option were selected, then the SE 8th Station would not be built, but the residents would still be served by the East Main Station, which would be located farther north. SE 15th Street might be closed, which would result in vehicles, pedestrians, and bicyclists needing to enter and/or exit the Bellefield Office Park off of SE 8th Street.

Just one of the businesses that would be affected by Bellevue Way Alternative (B1) was identified as important to the neighborhood. The Chevron station located on the corner of Bellevue Way SE and 108th Avenue SE provides an important service to the area, which is not provided by other business in the immediate vicinity.

TABLE 4.4-2
Factors Considered in Assessing Impacts on Neighborhoods Within Segment B

Alternative	**Potential Impacts by Alternative**			
	Displacements	**Visual/Physical Intrusion**	**Noise Impacts**	**Traffic/Access Changes**
Preferred 112th SE Modified Alternative (B2M) to *C11A*	0 businesses 1 residence	Removing vegetation and adding other project components (e.g., retained cut and overhead guideway) would result in visual change along Bellevue Way SE to the Bellevue Way/112th Avenue SE interchange but not result in visual impact. Lower profile of the guideway minimizes visual impacts along Bellevue Way SE. In addition, light rail would be more visible to residences along 112th Avenue SE than *Preferred Alternative B2M* to *C9T*.	Noise impacts would be mitigated using a combination of sound walls, track lubrication at curves, building sound insulation, or special trackwork at crossovers and turnouts.	Right-in/right-out on 112th Avenue SE and Bellevue Way SE Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride
Preferred 112th SE Modified Alternative (B2M) to *C9T*[a]	0 businesses 1 residence	Removing vegetation and adding other project components (e.g., retained cuts and overhead guideway) would result in visual changes impacts along Bellevue Way SE to the Bellevue Way/112th Avenue SE interchange.	Impacts would be the same as *Preferred Alternative B2M*.	Potential loss of access to SE 15th Street Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride
Bellevue Way Alternative (B1)	2 businesses 12 residences	Intrusions would be the same as *Preferred Alternative B2M* to *C9T*; in addition, retaining walls on the west side of Bellevue Way SE would result in visual impact.	Impacts would be the same as *Preferred Alternative B2M*.	Right-in/right-out on Bellevue Way SE Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride
112th SE At-Grade Alternative (B2A)	0 businesses 4 residences	Intrusions would be the same as *Preferred Alternative B2M* to *C9T;* in addition, elevated structures on Bellevue Way SE would be more visible from nearby residences than with Alternative B1, resulting in a visual impact. Removing vegetation from the west side of Bellevue Way SE would open up views east for some residents. Light rail in the median along 112th Avenue SE would alter visual character of the area for those in close proximity.	Impacts would be the same as *Preferred Alternative B2M*.	Impacts would be the same as Preferred Alternative B2M to C11A
112th SE Elevated Alternative (B2E)	0 businesses 1 residence	Intrusions would be the same as *Preferred Alternative B2M* to *C9T*. In addition, elevated structures on Bellevue Way SE would be more visible from nearby residences and would impact eastward views towards the Mercer Slough Nature Park, resulting in a visual impact. Elevated structures on 112th Avenue SE would be more visible than with *Preferred Alternative* but generally consistent with the existing boulevard-like character.	Impacts would be the same as *Preferred Alternative B2M*.	Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride
112th SE Bypass Alternative (B3)	0 businesses 4 residences	Intrusions would be the same as Alternative B1.	Impacts would be the same as *Preferred Alternative B2M*.	Right-in/right-out on 112th Avenue SE Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride
B3 - 114th Extension Design Option	14 businesses 4 residence	Intrusions would be the same as Alternative B1.	Impacts would be the same as *Preferred Alternative B2M*.	Design options to include signals and U-turn movements to preserve access south of the South Bellevue Park-and-Ride.
BNSF Alternative (B7)	6 businesses 0 residences	Elevated structures passing north of I-90 Trail (part of Mountains-to-Sound Greenway) would be viewed by trail users and residences along 118th Avenue SE.	Impacts would be the same as *Preferred Alternative B2M*.	No changes

[a] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

which is not provided by other business in the immediate vicinity.

Relocating this business would result in an impact on those in the surrounding neighborhood who use this business, resulting in additional travel for gasoline purchases, but this impact in combination with other neighborhood impacts would not degrade neighborhood quality. No new barriers for social interaction would be created by this alternative.

Impacts on community and public services would be minor. Although Alternative B1 travels directly in front of the Bellevue Fire Department Station 1, it would not result in impacts on access and egress because there would be a signal with left-turn access allowed into and out of the fire station. Because constructing sound walls would not be feasible in all locations, Alternative B1 would result in the greatest number of noise impacts compared with the other Segment B alternatives.

Table 4.4-2 lists impacts on the neighborhood quality from 112th SE At-Grade Alternative (B2A), which would be generally minor and have two additional residential displacements compared with *Preferred Alternative B2M*. North of the 112th Avenue SE intersection, widening would remove the existing landscaped median from 112th Avenue SE and Bellevue Way. A longer portion of this median is removed under Alternative B2A than *Preferred Alternative B2M to C11A*. All existing community resources would be maintained. There would be increased neighborhood access to transit through the SE 8th Station.

112th SE Elevated Alternative (B2E) would have similar impacts on neighborhood quality and generally follows the same route as Alternative B2A, except that it continues elevated all the way to the station at SE 8th Street. Alternative B2E would not create any new barriers to social interaction or traffic circulation. Alternative B2E would have the same number of displacements as *Preferred Alternative B2M* (i.e., no businesses and one residence) but would offer more of a visual and physical presence along Bellevue Way SE. North of 112th Avenue SE intersection, Alternative B2E would be elevated and retain the landscaped median, thus maintaining the general boulevardlike character of 112th Avenue SE. All community resources would be preserved, and neighborhood quality would be slightly affected by visual changes for residences on the edges along Bellevue Way and 112th Avenue SE.

For the most part, 112th SE Bypass Alternative (B3) follows the same route as *Preferred Alternative B2M*. Neighborhood impacts would be generally the same, except it would not add the SE 8th Station and, thus, would not provide new accessibility for surrounding residents. At the northern end, it would pass through parking lots, behind office buildings, across an undeveloped open area, and remove some landscaped parking strips. No community resources would be affected, nor would new barriers to social interaction result. Neighborhood quality would be maintained.

The impacts from Alternative B3 - 114th Extension Design Option would be similar to those described above under *Preferred Alternative B2M* until approximately SE 15th Street. North of SE 15th Street, the alternative would curve to the east away from the residential neighborhood and through the Bellefield Office Park, displacing some businesses. There is no SE 8th Station associated with the B3 - 114th Design Option. No community resources would be affected, nor would there be any new barriers to social interaction.

Overall, Alternative B7 would have little impact on neighborhood quality because much of it would follow the I-90 and former BNSF Railway corridors. There would be no changes in access or circulation, and visual and physical intrusion would be minimal because, for the most part, the project would be consistent with the existing rail corridor and the I-90 structure over the Mercer Slough Nature Park. This and all other community resources along this route would remain intact and accessible. Neighborhood quality and social interaction would be maintained.

Segment C

Because the Downtown Bellevue area is densely developed, it was considered important to identify the staging areas needed to construct Segment C to evaluate the associated potential impacts. Segment C staging areas would be located at either end of the segment in Downtown Bellevue and at each station (refer to Chapter 2 for information on staging area locations). Staging areas would acquire properties in different areas, depending on the alternative selected and the specific connection from Segment B. The impacts from the use of the staging areas are discussed later in this section under Section 4.4.3.3. Following construction, most of these areas would be available for redevelopment. For the most part, the Segment C alternatives would follow the existing roadway grid of the highly urbanized Downtown Bellevue. There would be displacements of residences and businesses, some minor changes to property access, the removal of vegetation, and the addition of new structures, which can affect neighborhood quality. The Segment C alternatives that involve tunneling would have minimal impacts because they would be underground and most of the impacts, such as displacement, are anticipated only in the station areas and staging areas. Most of the Segment C alternatives would have minimal property access impacts. Impacts on pedestrian and bicycle circulation within Downtown Bellevue are expected to be minimal because existing pedestrian crossings and bicycle routes would be maintained and the alternatives would not alter the location of future bicycle routes identified in the Bellevue Comprehensive Plan. Overall, the impact of direct property acquisitions, lower visual quality, and access revisions are not expected to markedly alter the overall land use or development character of the neighborhoods in Segment C. There would be no indoor noise impacts after mitigation for any of the Segment C alternatives. Table 4.4-3 summarizes the factors used to assess impacts on neighborhoods by Segment C alternative, and a discussion follows.

Preferred 108th NE At-Grade Alternative (C11A) would result in changes to the Surrey Downs neighborhood along 112th Avenue SE and Main Street but would not result in any negative impacts on the overall neighborhood quality. *Preferred Alternative C11A* would acquire residential properties, including 6 single-family and 41 multifamily units that currently face 112th Avenue SE. The light rail guideway would be consistent with the arterial transportation character of 112th Avenue SE. Currently, 112th Avenue SE acts as a boundary for the eastern portion of the neighborhood. While widening the transportation corridor to include light rail would change the edge of the community, acquiring these residences would not bisect the neighborhood and not negatively affect the overall quality of the Surrey Downs neighborhood.

Most residences that would be acquired are not in character with the overall Surrey Downs neighborhood, and due to their position facing 112th Avenue SE with no direct access into the Surrey Downs neighborhood, relocating them would not impact the larger neighborhood's cohesion. After construction there would be a buffer of approximately 50 feet between the light rail project and the neighborhood. This buffer would include landscaping and provide a visual buffer and a potential open-space amenity for nearby residents. Sound walls would be installed on the guideway or retained fill along the west side of 112th Avenue SE to mitigate noise impacts.

Preferred Alternative C11A would close the SE 4th Street access to 112th Avenue SE. Residents that use this access would need to use alternate access at SE 1st Place or elsewhere in the neighborhood. Additionally, residents accessing Main Street via 110th Place and 110th Street would be redirected to the intersection at 108th Avenue. These changes would require some residents to use a more circuitous route, but the low number of trips that this would redirect would not result in traffic impacts that would affect neighborhood quality or social interaction.

Visual changes would be noticeable to some residents adjacent to the project, especially near the intersection of 112th Avenue SE and Main Street where the alternative would be elevated; however, the alternative would not lower the corridor's overall visual quality and, therefore, would not impact the overall neighborhood quality. *Preferred Alternative C11A* would impact one community facility by acquiring a portion of Surrey Downs Park, and would require reviewing and amending of the City's adopted master plan for the park.

The 108th Station would be adjacent to the neighborhood, and no other land use changes would be expected of the single-family residential zoning. For those near the station, there would be benefits associated with increased transit access. In addition, the neighborhood is an established Residential Parking Zone, which minimizes the possibility of hide-and-ride parking. There would be no noise impacts on the residences in the Surrey Downs Neighborhood after mitigation. There would also be a landscaped buffer and transition area south of Main Street and the commercial area to the north, which is consistent with the City of Bellevue's Comprehensive Plan policy S-DT-125. This policy has to do with transitions between downtown and the residential neighborhood to the southeast. East of the Bellevue Transit Center Station the trackway would be located in a commercial area and there would be no negative impacts within the Wilburton or Bel-Red neighborhoods associated with the East Link Project.

Preferred 110th NE Tunnel Alternative (C9T) would result in similar impacts to those identified above for *Preferred Alternative C11A*. Impacts on the Surrey Downs neighborhood along 112th Avenue SE would be the same as those described above under *Preferred Alternative C11A*.

The differences would be in neighborhood access from 112th Avenue SE—the 108th Station is not associated with *Preferred Alternative C9T*—and impacts on Surrey Downs Park. *Preferred Alternative C9T* would close access to 112th Avenue SE from SE 1st Place, and SE 4th Street would be redirected to a new access point at the intersection of SE 6th Street and 112th Avenue SE with signalized access to 112th Avenue SE. Impacts

TABLE 4.4-3
Factors Considered in Assessing Impacts on Neighborhoods Within Segment C

Alternative	**Potential Impacts by Alternative**			
	Displacements[a]	**Visual/Physical Intrusion**	**Noise Impacts**	**Traffic/Access Changes**
Preferred 108th NE At-Grade Alternative (C11A)	39 to 40 businesses 0 to 46 residences	Vegetation and residences would be removed on west side of 112th Avenue SE and south of Main Street, but the area would be landscaped.	Noise impacts would be mitigated using a combination of sound walls, track lubrication at curves, sound insulation, or special trackwork at crossovers and turnouts.	Changes in circulation in Surrey Downs neighborhood
Preferred 110th NE Tunnel Alternative (C9T)[b]	17 to 18 businesses 0 to 46 residences	Vegetation and residences would be removed on west side of 112th Avenue SE and south of Main, but the area would be landscaped.	Impacts would be the same as *Preferred Alternative C11A*.	Changes in circulation in Surrey Downs neighborhood
Bellevue Way Tunnel Alternative (C1T)	21 businesses 91 residences	Intrusion would be minimal because much of the route is underground.	Impacts would be the same as *Preferred Alternative C11A*.	Minimal because light rail system operates below ground
106th NE Tunnel Alternative (C2T)	13 to 20 businesses, 0 to 12 residences	Intrusion would be minimal because much of the route is underground.	Impacts would be the same as *Preferred Alternative C11A*.	Minimal because light rail system operates below ground
108th NE Tunnel Alternative (C3T)	15 to 22 businesses, 7 to 19 residences	Mature vegetation would be removed in McCormick Park, and the presence of the light rail transition would result in visual impacts that could be fully mitigated.	There would be no impacts after mitigation.	Changes in access to and from the Northtowne Neighborhood.
Couplet Alternative (C4A)	36 to 37 businesses, 8 residences	Intrusions would be the same as Alternative C3T.	Impacts would be the same as *Preferred Alternative C11A*.	Changes in circulation along 110th Avenue NE and 108th Avenue NE in Downtown Bellevue Neighborhood
112th NE Elevated Alternative (C7E)	29 to 30 businesses, 0 residences	Intrusions would be minimal due to the scale and design of the surrounding facilities, including I-405.	There would be no impacts after mitigation.	Minimal because light rail system operates above ground
110th NE Elevated Alternative (C8E)	33 businesses, 2 residences	Intrusions would be the same as with Alternative C3T. In addition, an elevated structure (trackway and station) would be introduced over 110th Avenue NE, which would be out of context with the pedestrian environment near the Bellevue Transit Center and the parklike setting near Bellevue City Hall.	There would be no impacts after mitigation.	Right-in/right-out on 110th Avenue NE
110th Avenue NE At-Grade Alternative (C9A)	17 to 18 businesses, 0 to 1 residences	South of Main Street, the elevated trackway and straddle bents would be out of context with the area, resulting in visual impact.	Impacts would be the same as *Preferred Alternative C11A*.	Right-in/right-out on 112th Avenue NE and 110th Avenue NE
114th Avenue NE Elevated Alternative (C14E)	24 businesses, 0 residences	Intrusions would be similar to Alternative C7E. The elevated walkway and tent structures would block views to the east.	There would be no impacts after mitigation.	Minimal because light rail system operates above ground

[a] The range reflects differences between connectors from Segment B alternatives.

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

related to access would require a more circuitous route for some residents, but the low number of trips that this would redirect would not result in traffic impacts that would affect neighborhood quality. There also would be permanent property acquisition impacts on Surrey Downs Park. *Preferred Alternative C9T* would realign SE 4th Street through the park, but no active recreation facilities would be affected. C9T - Main

Street Station Design Option would provide additional accessibility to residents in this area. Impacts east of the Bellevue Transit Center Station would be the same as those described for *Preferred Alternative C11A*. Impacts from the East Main Station Design Option would be similar to those in C9T.

The Bellevue Way Tunnel Alternative (C1T) would have the highest number of displacements due to the displacement of three multifamily buildings. Because of the urban nature of Downtown Bellevue and surrounding area, however, relocation opportunities are expected to be readily available within a number of mixed-use developments and multifamily units existing, currently planned, or under construction. Given the abundance of available residential dwellings, both single-family and multifamily, in the surrounding area, even if the residents decided to move elsewhere, there would be no negative impact on the neighborhood's cohesion.

Much of the C1T route would be underground (including the Old Bellevue and Bellevue Transit Center stations) and therefore would not change social interaction. The transition of the alternative from tunnel to elevated along NE 6th Street would be visible but consistent with the existing character and visual quality of the area nearby. Traffic movements could become slightly more circuitous to Meydenbauer Center and City of Bellevue offices, but access to these community resources would not be diminished. Neighborhood quality would be enhanced with improved transit accessibility and reliability from two to three light rail stations serving downtown neighborhoods.

Neighborhood impacts and benefits with 106th NE Tunnel Alternative (C2T) would be generally the same as with *Preferred Alternative C9T*, the primary difference being fewer displacements. Regardless of which connector and staging area is used, this alternative would result in the least number of displacements in comparison to the other alternatives in Segment C, and project components would be consistent with the visual character of the surrounding areas. Alternative C2T would have access and circulation impacts similar to those described for Alternative C1T.

Neighborhood impacts and benefits with 108th NE Tunnel Alternative (C3T) would be generally the same as with *Preferred Alternative C9T* and Alternative C2T. Like other tunnel alternatives, this alternative is mostly underground, and impacts would occur primarily at the staging areas (see Section 4.4.3.3, Impacts During Construction, below). Along NE 12th Street, Alternative C3T would alter McCormick Park and result in visual impacts that could not be fully mitigated. This park serves as a neighborhood buffer from downtown business traffic and activities. Following construction, the park would be enlarged by converting the staging area; therefore the buffer would be replaced and the neighborhood quality preserved. A cul-de-sac with access from NE 12th Street would be redirected to access 108th Avenue NE. This would buffer some homes from traffic and generate a few more traffic trips from the redirected residents. No other changes to property access and circulation would be necessary because Alternative C3T mainly operates underground; therefore, no barriers to social interaction would be created.

The Couplet Alternative (C4A), while aboveground, would have similar impacts and benefits as the tunnel alternatives. Although the changes would be more noticeable, the at-grade profile and location in the existing street right-of-way through downtown is consistent with the urban environment and streetscape. Also, the at-grade light rail stations would be more accessible to users than the elevated tunnel alternatives because there are no stairs or elevators. The impacts from the portion of the alternative that would pass along NE 12th Street would be similar to those described for Alternative C3T. While community resources such as McCormick Park would be impacted by the presence of light rail, they would also benefit from increased accessibility. The vibration impact described under Alternative C3T would also occur with Alternative C4A.

Alternative C4A would affect traffic circulation along 110th Avenue NE and 108th Avenue NE in Downtown Bellevue. For the safety of light rail and traffic movement, light rail would travel counterflow to traffic, north along 110th Avenue NE, and south along 108th Avenue NE. There would be some inconveniences of restricted turning movements, but for the most part access would be preserved and no barriers created. For emergency access, the trackway would have mountable curbs. Overall, the neighborhood quality would be enhanced with new transit access by this alternative without adverse impacts on quality of life.

North of Main Street, the 112th NE Elevated Alternative (C7E) elevated profile and pedestrian crossing structure would pass along 112th Avenue NE and would be noticed, but it would be consistent with the character of this section of 112th Avenue NE because of the visual association with large transportation features, such as access to and from I-405. Because Alternative C7E is elevated along 112th Avenue NE, there would be minimal impacts on property access and circulation along this alternative and therefore no impact on social interaction. Overall, this alternative would not impact community resources or add barriers to social interaction, and it would enhance transit accessibility and offer a benefit to neighborhood quality.

The 110th NE Elevated Alternative (C8E) elevated profile and stations at the Bellevue Transit Center would affect the visual environment for residents in nearby multifamily buildings. Circulation impacts would be minor because U-turn movements would be allowed at signalized intersections. For the multifamily residential units located along 110th Avenue NE between NE 10th Street and NE 12th Street, noise impacts would be mitigated, but the visual intrusion cannot be fully mitigated. These impacts would not change the overall neighborhood social interaction, affect community resources, or adversely reduce the neighborhood quality.

Operations impacts on the Bellevue Transit Center from 110th NE At-Grade Alternative (C9A) would be similar to *Preferred Alternative C11A*, except light rail would be located on 110th Avenue NE. East of the Bellevue Transit Center, Alternative C9A would be the same as *Preferred Alternative C11A*.

Impacts during light rail operations from 114th NE Elevated Alternative (C14E) would be similar to Alternative C7E except the guideway is located farther east adjacent to 114th Avenue NE and crosses over I-405 north of NE 6th Street. The Bellevue Transit Center Station would be 1,300 feet away from the existing Bellevue Transit Center, which reduces the accessibility for transit transfers.

Segment D

The Cities of Bellevue and Redmond have updated their comprehensive and neighborhood plans to encourage TOD within the Bel-Red Corridor and Overlake Village area of the Overlake Neighborhood (see Section 4.2, Land Use, for further description of plans and policies). This analysis compares the impacts of Segment D alternatives with the intent of these neighborhood plans while considering impacts on immediate neighborhood uses. Table 4.4-4 summarizes factors considered in assessing impacts on neighborhoods from Segment D alternatives.

TABLE 4.4-4
Factors Considered in Assessing Impacts on Neighborhoods Within Segment D

	Potential Impacts by Alternative			
Alternative	**Displacements**[a]	**Visual/Physical Intrusion**	**Noise Impacts**	**Traffic/Access Changes**
Preferred NE 16th At-Grade Alternative (D2A)[b]	34 businesses, 0 residences	Intrusion would be minimal because the light rail system would be consistent with the urban environment.	There would be no impacts after mitigation; noise impacts would be mitigated using a combination of sound walls, track lubrication at curves, building sound insulation, or special trackwork at crossovers and turnouts.	Right-in/right-out on NE16th Street and 136th Avenue NE where light rail system is at-grade
D2A - NE 24th Design Option	69 businesses 0 residences	Intrusion would be the same as *Preferred Alternative D2A*.	Impacts would be the same as *Preferred Alternative D2A*.	Driveways along the west side of 152nd Avenue NE and the north side of NE 24th Street are closed
NE 16th Elevated Alternative (D2E)	42 businesses, 0 residences	Intrusion would be the same as *Preferred Alternative D2A*.	Impacts would be the same as *Preferred Alternative D2A*.	Minimal because light rail system is elevated
NE 20th Alternative (D3)	74 businesses, 0 residences	Intrusion would be the same as *Preferred Alternative D2A*.	Impacts would be the same as *Preferred Alternative D2A*.	Right-in/right-out on NE16th Street and 136th Avenue NE where light rail system is at-grade and restricted along NE 20th Street
SR 520 Alternative (D5)	79 businesses, 0 residences	Intrusion would be the same as *Preferred Alternative D2A*.	Impacts would be the same as *Preferred Alternative D2A*.	Minimal because light rail system is located off local roadways.

[a] The range reflects differences between connectors from Segment C Alternatives (either from former BNSF Railway or from NE 12th Street).
[b] Impacts with D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

The new light rail stations have a potential to act as a catalyst for redevelopment consistent with recently adopted plans. Adjacent residential neighborhoods would benefit from increased mobility options and additional services created from station development. Like the stations located in Bellevue, a station located within the Overlake Village area would support the City of Redmond in implementing the recently adopted land use plans. The Overlake Transit Center Station would support the existing land use and increase mobility for expanding numbers of Microsoft and other nearby office employees.

Overall impacts on property access and circulation in Segment D are expected to be focused along NE 15th/16th Street, NE 20th Street, and 152nd Avenue NE.

Preferred NE 16th At-Grade Alternative (D2A) would have little impact on existing neighborhood quality because the trackway would primarily be parallel to and north of the new NE 15th Street corridor and adjacent to the SR 520 right-of-way.Property acquisition would not be adverse to the neighborhood because of the planned land use changes for the area.

There would be no differences in impacts on community resources between *Preferred Alternative D2A* and the D2A - 120th Design Option. The D2A - NE 24th Design Option would displace additional businesses compared with *Preferred Alternative D2A*. With the D2A - NE 24th Design Option, driveway access from the north side of NE 24th Street to commercial business between 148th Avenue NE and 151st Place NE would be permanently removed to prevent left-turning vehicles from crossing the at-grade track. Similarly, western access to and from the business park along 152nd Avenue NE between NE 24th Street and NE 28th Street would be closed. Vehicle circulation within surrounding office parks would likely be rerouted onto 151st Place NE.

Although this would affect access to businesses, it is not considered a barrier to social interaction. The new transit stations at planned TOD nodes are considered new centers for increasing social interaction. No community resources would be affected. The influence of *Preferred Alternative D2A* on the neighborhood quality of the area would be minimal to the existing neighborhood and would support the planned mix-use development for the Bel-Red neighborhood.

NE 16th Elevated Alternative (D2E) is an elevated version of *Preferred Alternative D2A* and would have little impact on neighborhood quality. The elevated stations in the western part of the alternative would be compatible in character and would not change the visual quality. Impacts in the eastern portion would be similar to those described for *Preferred Alternative D2A* and D2A - NE 24th Design Option except the lost driveway access would be on the south side of NE 24th Street.

Under Alternative D2E, the route runs along the side of NE 16th Street and 136th Avenue NE, thus minimizing impacts on property access and circulation. Access from NE 24th Street to commercial businesses between 148th Avenue NE and 151st Place NE would be affected as described for *Preferred Alternative D2A*. Like *Preferred Alternative D2A*, there would be no impact on community resources and no barriers to social interaction, but rather enhanced centers for social interaction. Neighborhood quality is expected to improve with D2E.

West of approximately 140th Avenue NE, the impacts of NE 20th Alternative (D3) would be essentially the same as those described for *Preferred Alternative D2A*. Alternative D3 would affect access and circulation along NE 16th Street and 136th Avenue NE similar to those of *Preferred Alternative D2A*, but Alternative D3 would have more property access and circulation issues because it would operate in the median along NE 20th Street and 152nd Avenue, affecting low-density commercial establishments. Although this would affect access to businesses, it is not considered a barrier to social interaction. Also, major intersections would preserve the ability to access businesses on either side of NE 20th. The new transit stations at planned TOD nodes are considered new centers for increasing social interaction. No community resources would be affected. The influence of Alternative D3 on the existing neighborhood quality of the area would be minimal, if not beneficial over time.

The SR 520 Alternative (D5) would have no adverse impacts on neighborhood quality, social interaction, or community resources because it would primarily follow the former BNSF Railway corridor and the south side of SR 520. Alternative D5 also would have the least property access and circulation impacts because most of the alternative is outside the roadway right-of-way.

Similar to *Preferred Alternative D2A* with the NE 24th Design Option and to Alternative D2E, the western driveway access along 152nd Avenue NE between NE 24th Street and NE 28th Street would be closed. However, this alternative would not offer the same neighborhood benefits of the other Segment D alternatives because it does not include the 120th and 130th Stations associated with *Preferred Alternative D2A*. The presence of light rail for this alternative may not have as much influence on Transit Oriented

Development in the Bel-Red Neighborhood, and therefore less benefit on the neighborhood quality.

Segment E

Table 4.4-5 summarizes factors considered in assessing impacts on neighborhoods from Segment E alternatives. A large portion of the light rail alternatives in this segment travels parallel to SR 520 and, therefore, would not affect property access or adjacent neighborhoods. Because all alternatives use the same route in this section of Segment E, the discussion focuses on differences after the alternatives diverge at West Lake Sammamish Parkway NE. Also, all Segment E alternatives use a substantial portion of the former BNSF Railway corridor parallel to NE Redmond Way, so access to and circulation around the Redmond Town Center and surrounding businesses and neighborhoods would not be affected.

Preferred Marymoor Alternative (E2), Redmond Way Alternative (E1), and Leary Way Alternative (E4) would not affect pedestrian circulation on sidewalks within or surrounding the Redmond Town Center or Downtown Redmond.

With *Preferred Alternative E2*, the route along Marymoor Park would be scarcely visible north of SR 520 because of the screening effect of trees that follow Bear Creek and the fact that the alternative would be constructed at-grade on the south side of the raised embankment on which SR 520 is built. The alternative would impact 2.0 acres of Marymoor Park and would be more visible from parts of Marymoor Park, particularly the sports fields at the north end of the park. *Preferred Alternative E2* would be similar in character to SR 520 (but less visible). The alternative would also realign and relocate a planned extension of the East Lake Sammamish Trail, but project operation would not affect access or impair views from the trail.

The Downtown Redmond Station with *Preferred Alternative E2* would enhance transit accessibility to the Redmond Saturday Market that occurs near the intersection of Leary Way NE and the former BNSF Railway corridor, in the northwest corner of the Redmond Town Center.

The E2 - Redmond Transit Center Station Design Option would have a greater impact on properties than the other alternatives due to the displacement of a 60-unit and 62-unit apartment buildings. It would also have more impact on property access and circulation than the other alternatives because it proceeds at-grade in the median of 161st Avenue NE between Cleveland Street and NE 85th Street. Midblock property access would be restricted to only allow right turns in and out of the driveways. To minimize vehicle recirculation, NE 83rd Street and 161st Avenue NE would be signalized, and this intersection as well as NE 80th Street and NE 85th Street would allow U-turn movements.

While these are more impacts on the neighborhood than other Segment E alternatives, this terminus station would augment the Redmond Transit Center, and therefore would be compatible with the neighborhood when in operation. There would be no adverse impacts on community resources, neighborhood quality, or social interaction—only benefits of increased accessibility to reliable transit.

TABLE 4.4-5
Factors Considered in Assessing Impacts on Neighborhoods within Segment E

	Potential Impacts by Alternative			
Alternative	**Displacements**	**Visual/Physical Intrusion**	**Noise Impacts**	**Traffic/Access Changes**
Preferred Marymoor Alternative (E2)	8 businesses, 2 residences	Intrusion would be minimal because the light rail system would be consistent with the urban environment.	Noise impacts would be mitigated using a combination of sound walls, track lubrication at curves, building sound insulation, or special trackwork at crossovers and turnouts.	Changes would be minimal because light rail primarily within existing transportation right-of-way
E2 - Redmond Transit Center Station Design Option	23 businesses, 126 residences	Intrusion would be the same as *Preferred Alternative E2*.	Impacts would be the same as *Preferred Alternative E2*.	Right-in/right-out on 161st Avenue NE
Redmond Way Alternative (E1)	7 businesses, 2 residences	Intrusion would be the same as *Preferred Alternative E2*.	Impacts would be the same as *Preferred Alternative E2*.	Minimal because light rail primarily within existing transportation right-of-way
Leary Way Alternative (E4)	7 businesses, 2 residences	Removing vegetation would temporarily impact the visual quality along Leary Way.	Impacts would be the same as *Preferred Alternative E2*.	Minimal because light rail primarily within existing transportation right-of-way

The other Segment E alternatives would also be near the Redmond Saturday Market, but no impacts are anticipated, and the Redmond Town Center Station would provide improved accessibility. The other alternatives would also require minor realignment of the East Lake Sammamish Trail but would not affect access.

Alternative E1 would not adversely impact adjacent neighborhoods because it would result in only two residential relocations and only minor visual impacts as it travels between SR 520 and NE Redmond Way. The route along West Lake Sammamish Parkway NE would require removing a number of trees on the hillside in front of a large condominium complex. This would change the character of the residences at the edge of this neighborhood but would not diminish the overall neighborhood quality.

This structure and the removal of the trees on the south edge of Luke McRedmond Landing Park would result in visual change, but the visual character of the park itself and transportation facilities adjacent to the park would not change. No other impacts on community resources would result from this alternative.

Alternative E1 would not create barriers to social interaction because it would operate almost fully outside the roadway right-of-way. Property access on the south side of Redmond Way, near the 159th Place NE intersection, may have their access altered to accommodate this alternative. The overall neighborhood quality would not be adversely affected.

Alternative E4 would have impacts similar to those of Alternative E1 along West Lake Sammamish Parkway NE, except that the light rail along Leary Way would require the removal of trees along the south side of Leary Way NE, which is the formal entry into Downtown Redmond, and the relocation of the Justice White House, an important historic resource in the settlement of Redmond. The relocation would not negatively impact the neighborhood because it would be relocated in the same general vicinity. There would be a visual impact for a portion of the neighborhood due to the removal of mature trees along a portion of Leary Way NE in the Town Center open space. However, Sound Transit is proposing mitigation that would partially screen the light rail guideway, and minimize the visual effect on appearance of the Leary Way NE entry into Downtown Redmond. While the removal of the trees would impact those who travel along Leary Way NE, it would not result in adverse impacts on the overall neighborhood quality.

Alternative E4 would also have minimal impact on property access and circulation because the alternative operates almost fully outside the roadway right-of-way. This would require removing some land from the Redmond Saturday Market, but it would be able to operate, and the Redmond City Center Station would provide improved accessibility to the market. No barriers to social interaction would be created, and the alternative would provide enhanced transit access. Because the impact would be on only one building, there would be no adverse impacts on the surrounding neighborhood. The impacts of Alternative E4 would not reduce the neighborhood quality, and the increased accessibility would enhance the neighborhood.

Maintenance Facility

The MF1 would require relocation of the Bellevue Public Safety Training Center, but this would not result in negative impacts on fire and emergency medical services because this facility is primarily used for training and therefore more easily relocated. The MF2, MF3, or MF5 would not result in negative impacts on community facilities. The presence of a maintenance facility in Bellevue (MF1, MF2, or MF3) might limit the anticipated TOD that is identified in the Bellevue comprehensive and neighborhood plans for this area. But the sites have been located in areas that can be screened and would not impact the continuity of the surrounding neighborhood cohesion. No additional impacts on neighborhoods or community facilities are anticipated as a result of the maintenance facilities during operation.

4.4.3.3 Impacts During Construction

Impacts Common to All Alternatives

Similar to the impacts during operation, impacts from construction activities would potentially affect neighborhood quality, social interaction, community resources, and safety and security.

Construction would temporarily affect neighborhood quality. Construction of East Link would affect any given neighborhood for approximately 2 to 5 years, where tunnel construction is generally longer than at-grade and elevated construction (See Chapter 2 for more detail information). Activities related to building the project would include the presence and movement of equipment and materials, clearing and exposure of soils, introduction of lights for nighttime work, storage of construction materials, and general visual changes in the viewed landscape during the period of building the project.

Temporary increases in noise, dust, and traffic congestion would occur along the corridor and at staging areas during construction. Adjacent neighborhoods may experience increased difficulty accessing residential, commercial, and office properties because of road closures, construction equipment, and retained cut construction activities. Roadway closures or lane closures could result in detours and cut-through traffic through neighborhoods and community facilities. Construction would affect nearby neighborhoods to varying degrees for varying amounts of time.

Construction would also require a substantial amount of earthmoving, particularly for the tunnel alternatives. The average number of truck trips per day and per hour for each alternative is discussed in Chapter 3. Haul trucks are expected to arrive and depart from I-90, I-405, and SR 520 to access local construction sites. Truck trips would be required to follow designated haul routes to minimize impacts on neighborhoods. It is anticipated that the primary arterials would be used for the haul routes, and because these arterials are located along the edge of the neighborhoods, no impacts on the overall neighborhood are anticipated.

Although some residents and businesses in the immediate area of construction would experience impacts, the overall neighborhood cohesion would not be permanently affected. Sound Transit would implement measures to minimize construction-related parking and travel in the adjacent residential neighborhoods to the extent possible. During construction, Sound Transit would implement measures (i.e., advertisements and signage) to help businesses maintain open accessible conditions as well as continue to perform public outreach (i.e., public involvement meetings, website, and telephone to allow residents and businesses to voice their concerns and for Sound Transit to respond to any concerns). Refer to Section 4.3, Economics, for additional information on mitigation measures intended to reduce the impacts of construction on businesses.

In general, Sound Transit would maintain access to adjacent properties and prevent barriers to social interaction during construction to the extent possible. Because the alternatives follow major arterials, short-term impacts to pedestrian and vehicular circulation are not considered a barrier to interaction. Noise, dust, and congestion might affect the use of some community resources, and to some extent, the quality of the neighborhood's edge would be reduced for a period of time. Construction would temporarily affect portions of park resources to allow for construction or for staging areas. These closures would affect social interaction during construction, especially if the entire park or large sections of the park are affected. Section 4.17, Parkland and Open Space, describes the resources that would be impacted during construction. As described in Section 4.14, Public Services, Sound Transit would coordinate with public service providers prior to construction on detour routes and lane closures to ensure access for emergency response vehicles is maintained and minimize impacts on response times. The following outlines specific impacts on the neighborhoods by project segment.

Segment A

Neighborhoods would not be affected in Segment A. There could be negative impacts for those who reside close to construction activities; however, because construction activities and construction staging would be within the I-90 right-of-way and because I-90 is lower than the surrounding area, impacts are expected to be minor. Access for construction vehicles and haul routes would be from I-90, and construction traffic through the adjoining neighborhoods would be limited.

Segment B

Construction for the Segment B alternatives would primarily be located within existing transportation rights-of-way. Detour routes are available, with the exception of Bellevue Way SE south of 112th Avenue SE. Neighborhood traffic intrusion is expected to be low, with the exception of Bellevue Way SE heading north of the Y west of 112th Avenue SE. Increased traffic congestion as a result of the construction-related traffic disruptions could temporarily affect transit reliability and auto travel times on the local arterials.

Construction activities associated with *Preferred Alternative B2M* would be located farther east along Bellevue Way when compared to other Segment B alternatives along Bellevue Way SE. Because *Preferred Alternative B2M* is located east of Bellevue Way SE, it would minimize impacts on traffic on Bellevue Way due to lane closures. One lane along Bellevue Way SE would likely be closed for most of the construction period, with periods where additional lane closures could be required, depending on construction activity. It would also temporarily relocate the retail activities associated with the blueberry farm and the Eastside Heritage Center located in the Winters House. Other trail and park activities would be detoured to new points of access, but access would be maintained throughout construction.

Of the other alternatives in Segment B, Alternative B1 is predicted to require the most haul truck trips due to the relatively high amount of excavation and asphalt concrete pavement required. Alternative B1 would result in the greatest impacts on neighborhoods during construction due to the amount of new right-of-way required along Bellevue Way SE, which would disrupt those in the adjoining neighborhoods. Alternative B7 would result in the fewest impacts on the surrounding neighborhoods because much of the construction would be within the former BNSF Railway corridor. Alternatives B2A, B2E, and B3 would result in similar impacts as *Preferred Alternative B2M* because these alternatives follow essentially the same route along Bellevue Way SE and 112th Avenue SE.

Segment C

Construction would require mostly lane and/or road closures. Tunnels and underground stations may include cut-and-cover construction, tunnel-boring construction, and sequential excavation mining construction. Tunnel construction would likely last longer than construction for an elevated or at-grade section, creating a longer period of disruption to adjacent communities and supporting businesses.

Within Segment C, local, minor, and principal arterials would be affected by construction. Road closures range from none at staging areas and partial road closures for short-term durations, to full road closures. Detour routes would be available in the central business district, but commercial vehicles would have limited access in some cases. Construction vehicle traffic ranges from low to high, and neighborhood traffic intrusion would range from low to moderate.

Because Downtown Bellevue is so densely developed, it was considered important to identify the staging areas needed to construct Segment C in order to identify the associated potential impacts. Staging areas would be located at the northern and southern ends of Downtown Bellevue within Segment C to facilitate construction. The Segment C alternatives would also include a staging area at the stations (see Exhibits 2-52 through 2-60 in Chapter 2 for location of staging areas). Staging areas at the southern end of Alternatives C2T, C3T, or C4A would depend on the specific connection from Segment B.

The staging area locations with the greatest potential to affect neighborhoods are staging areas on the north half of Surrey Downs Park where the King County District Courthouse is located, the property southwest of Main Street/112th Avenue NE, the property along 112th Avenue NE, and property at McCormick Park. These staging areas are located adjacent to existing residences that could be affected by the noise, dust, and activity related to construction. Depending on the sensitivity of the surrounding land uses, a barrier could be used to buffer the adjacent land uses from noise and visual impacts where practical. Both the permanent impacts and the temporary construction impacts are discussed below for each alternative within Segment C.

Constructing *Preferred Alternative C11A* would potentially result in impacts related to construction activities near residences along 112th Avenue SE and Main Street. Although some residences would experience impacts, the overall neighborhood cohesion would not be affected. The area where properties would be acquired along 112th Avenue SE and Main Street would also be used for staging areas and to store building materials, equipment, and excavation materials. Construction would result in a temporary closure of a portion of Surrey Downs Park and users might experience increased noise, but access to the park would be maintained.

Because *Preferred Alternative C11A* follows 112th Avenue SE and Main Street, any short-term impacts on pedestrian and vehicular circulation are not considered a barrier to social interaction. Also, Sound Transit would maintain access to adjacent properties to the extent possible. Construction periods would comply with local noise ordinances. Where possible, mature trees would be preserved and noise barriers could be constructed prior to beginning construction. After construction, this area would be restored and would act as a buffer between light rail and the neighborhood. Within Downtown Bellevue, construction activities associated with the Bellevue Transit Center Station would require the temporary relocation of the transit bus bays.

Construction impacts with *Preferred Alternative C9T* would be located in similar areas of Surrey Downs Park and in a shorter-distance area along Main Street as those discussed under *Preferred Alternative C11A* but would involve cut-and-cover construction. Cut-and-cover construction activities have the potential to affect how neighborhood residents access businesses along 110th NE Avenue up to the Bellevue Transit Center. There would be times when roadways are closed due to excavation activities. Some portions of the roadway could possibly be temporarily covered (i.e., using steel plates), thus allowing work to continue below while traffic has access above. The properties used for staging are surrounded by mixed use and commercial uses within the urban downtown area, and would have no impact on single-family residential neighborhoods.

Alternative C1T would have the same construction impacts as *Preferred Alternative C9T*, except that the tunnel is longer and could affect access to Bellevue Arts Museum and the pedestrian path at approximately NE 6th Street between Bellevue Way and the Bellevue Transit Center. Alternative C1T would also relocate the transit bus bays during construction. The properties used for staging are surrounded by mixed use and commercial uses within the urban downtown area, so they would have no impact on single-family residential neighborhoods.

Like *Preferred Alternative C9T* and Alternative C1T, Alternative C2T would have similar construction impacts. Two of the possible staging areas at the south end, however, could potentially affect Surrey Downs located in the South of Downtown residential neighborhood. The first might affect the Surrey Downs neighborhood due to its location at the King County District Courthouse site and temporarily disrupt the quality of residential land uses during tunneling activities. However, this staging site would reduce the number of residential relocations with other connectors. After construction, the staging area would be available for redevelopment consistent with the master planning efforts for Surrey Downs Park.

If the connector from Alternative B2E is used, the relocated businesses and residences, which are isolated from the remaining residences in the neighborhood, would not be considered a negative impact on the overall neighborhood cohesion. Nearby residences would experience temporary disruption from adjacent project construction. When construction is completed, the land could be restored or used to create a park that would provide a buffer to transition between the Surrey Downs and Downtown neighborhoods as recommended in the Downtown Implementation Plan.

The third possible staging area for the southern end of Segment C is located at the East Main Station and is primarily within a commercial area and would not affect residential neighborhoods.

In addition to the possible staging areas and impacts on the Surrey Downs neighborhood described for Alternative C2T, Alternative C3T would use property at its north end that would potentially affect the Northtowne neighborhood. The staging area at McCormick Park would remove six single-family residences along the north side of the park. This represents a small area of the neighborhood. The impact would result in the temporary loss of the park to patrons as well as disruption of the buffer transition between the Northtowne and Downtown neighborhoods. Alternative C3T would include redesigning and reconstructing the park upon completion of the project. Nearby residents in the Northtowne neighborhood would have temporary disruption from adjacent project construction.

Alternative C4A would use primarily the same staging areas (i.e., south of Main Street and at McCormick Park) as Alternative C3T, with similar impacts. South of Main Street, Alternative C4A would require a smaller area.

The properties used for staging for Alternative C7E are surrounded by commercial uses within the urban downtown area, so they would have no impact on existing residential neighborhoods.

Alternative C8E would use the McCormick Park staging area, and impacts would be similar to those described for Alternative C3T. In addition, construction along 110th would affect several multifamily residences.

Impacts resulting from Alternative C9A would be similar to those described for Alternative C4A.

Impacts resulting from Alternative C14E would be similar to those described for Alternative C7E.

Segment D

Construction activities associated with *Preferred Alternative D2A* and the D2A - 120th Station Design Option would have no or limited impacts on neighborhoods because the area is associated with commercial- and industrial-related land uses, and there are no residential neighborhoods or community facilities nearby. Much of the western portions along this alternative may be under redevelopment at or following the construction of East Link. Collector, local, minor, and principal arterials would be affected by construction. Road closures would range from partial closures for short-term durations to full closures for long-term durations. Neighborhood traffic intrusion and construction vehicle traffic would be low because detours are generally available. A large segment of the alternative would be located adjacent to WSDOT right-of-way, thus minimizing the impacts on the local roadways. The D2A - NE 24th Design Option would require construction within the Overlake area, but the adjacent land uses are primarily commercial related and impacts would be the same as those described for above.

The other alternatives in Segment D would have similar impacts as those described for *Preferred Alternative D2A*. Impacts on neighborhoods would be minimal because these roads are surrounded by primarily industrial and commercial uses. Alternative D5 might result in even fewer disruptions because the route is mostly adjacent to SR 520 and away from the commercial corridors and major arterials.

Segment E

All Segment E alternatives travel along the south side of SR 520 and under NE 40th Street, NE 51st Street, and NE 60th Street in a retained-cut profile and then return to at-grade down to West Lake Sammamish Parkway NE. Within Segment E, local and collector arterials as well as state highways would be affected by construction. Barriers, such as road closures, would range from partial closures for short-term durations to full closures for long-term durations. Construction vehicle traffic is expected to be moderate, as would neighborhood traffic intrusion, because detour routes are generally available. In general, large portions of construction would be along or alongside of arterial or collector roads where noise is expected. Construction within the former BNSF Railway corridor is not expected to disrupt neighborhoods.

Preferred Alternative E2 would not likely result in any neighborhood impacts during construction because this alternative is primarily adjacent to the existing SR 520 right-of-way and within the former BNSF Railway corridor. The residential neighborhoods to the east of SR 520 might experience some noise impacts, but cohesion would not be affected. Users of the adjacent park facilities might experience increased noise, but access to and use of the facilities would not be impacted. The E2 - Redmond Transit Center Design Option would also impact the skate park near the existing Redmond Transit Center. This design option would close 161st Avenue NE during construction, which might affect access to businesses and some residential units, but all uses along this roadway have other access points.

In addition to the impacts with all Segment E alternatives, construction activities at the intersection of Leary Way NE and the former BNSF Railway corridor that would result from Alternative E4 may require temporary relocation of the Redmond Saturday Market and affect some multifamily residences. Because the market consists primarily of portable fixtures, temporary relocation elsewhere within the Redmond Town Center or Redmond is not expected to result in adverse impacts. Alternative E1 might affect traffic flow and business access on West Lake Sammamish Parkway and the residents on the bluff above the roadway, but no impacts on community cohesion are anticipated.

Maintenance Facility

No adverse impacts on the surrounding neighborhoods are anticipated from the construction of the maintenance facility alternatives because the facilities would be located within areas having primarily industrial uses. However, in the instance of MF1, which is close to the Children's Hospital Bellevue Clinic and Surgery Center and other medical and office land uses, there could be an increase in noise impacts. The only other exception is MF5, which would be constructed within an area surrounded by existing light industrial uses but could create noise and dust impacts near the Lake Washington Technical College Redmond Corporate Campus. This is not considered an adverse impact on the neighborhood quality.

4.4.4 Potential Mitigation Measures

Sound Transit would incorporate measures to try to minimize the impacts on neighborhood quality, social interaction, and safety and security. The East Link Project would primarily provide net benefits to neighborhood quality during operation, and therefore no mitigation would be necessary beyond mitigation described in other sections of the Final EIS. Project construction would result in temporary reduction of neighborhood quality due to construction barriers and reduced convenience in access and may result in impacts on use of community resources during construction.

Specific mitigation measures during project operation and construction are described in detail in other sections of this Final EIS, including Chapter 3 and Sections 4.1, 4.2, 4.3, 4.5, 4.6, 4.7, and 4.17. No additional mitigation measures related to social impacts, community, and neighborhoods would be required.

4.5 Visual and Aesthetic Resources

4.5.1 Introduction to Resources and Regulatory Requirements

Visual and aesthetic environments are the landscape's natural and cultural features that can be seen and that contribute to the public's appreciation and enjoyment of it. The visual environment encompasses elements from both the built and natural environments; these can include solitary built and natural landmarks (such as buildings, trees, and bodies of water) or entire landscapes. Impacts on the visual environment are defined in terms of the extent to which the project's presence would change the perceived visual character and quality of the environment.

This description of the existing visual conditions and assessment of changes associated with the East Link Project is based on the visual assessment system developed by the Federal Highway Administration (FHWA). The approaches and terminology used in this assessment are found in FHWA's *Visual Impact Assessment for Highway Projects* (FHWA, 1981). Appendix F4.5, Attachment 1, describes this assessment and how the existing visual quality categories were established and the degree to which the segment alternatives impacted visual quality categories. Sound Transit also assessed the project's consistency with visual resource goals and policies of relevant local comprehensive plans.

The study area for visual resources consists of the alternative viewsheds. Viewsheds are the areas from which the alternatives could be viewed. In general, the viewsheds for the East Link Project encompass the foreground viewing distance (within 0 to 0.5 mile from the viewer) but might vary depending upon elements in the landscape (such as terrain, vegetation, and buildings) that can block views of objects.

4.5.2 Affected Environment

Assessment activities for the affected environment included conducting site visits, examining aerial photographs, reviewing conceptual engineering drawings of the proposed alternatives, and preparing an existing conditions inventory. Preparing the existing conditions inventory relied in part on materials from other technical areas that influence the visual environment. These related technical areas are Land Use (Section 4.2); Social Impacts, Community Facilities, and Neighborhoods (Section 4.4); Ecosystem Resources (Section 4.8); and Parkland and Open Space (Section 4.17).

The existing conditions inventory described the existing visual character of the study area, identified the types of viewer groups that would see the alternatives, described their sensitivity to changes in the viewed environment (viewer sensitivity), and categorized the existing visual quality using three categories based on the FHWA system. The visual quality categories helped to assess changes in the visual environment that would occur with the East Link Project. Following are the three visual quality categories:

- **Low Visual Quality.** Areas that have low visual quality might have features that seem visually out of place, lack visual coherence, do not have compositional harmony, and contain eyesores.
- **Medium Visual Quality.** These areas are commonly occurring landscapes that are generally pleasant appearing but might lack enough distinctiveness, memorability, drama, and compositional harmony to place them in the high visual quality category.
- **High Visual Quality.** To be in this category, areas must be memorable, distinctive, unique (in a positive way), and intact—they can be natural, parklike, or urban (with urban areas displaying strong and consistent architectural and urban design features).

Exhibits 4.5-1 through 4.5-5 show the existing visual quality categories (low, medium, and high) by project segment (see Appendix F4.5, Attachment 1 for explanations of specific sections of alternative routes). In addition to categorizing the overall visual quality, Sound Transit selected a series of locations to provide more site-specific information. Because it is not possible to include all the important viewing locations near a proposed project, representative locations—or key observation points (KOPs)—are selected. KOPs are used to describe existing visual conditions and to analyze the effects of a proposed action on visual resources. The KOP locations were chosen after field reconnaissance of the alternative routes and after meetings with the planning departments of the Cities of Bellevue and Redmond.

In addition, important community features, identified in public workshops, were considered in determining KOP locations. Exhibits 4.5-1 through 4.5-5 depict the KOPs selected for the East Link Project.

More detailed information related to the KOPs, including photographs of the existing conditions at these locations as well as simulations of various alternatives, is provided in Appendix F4.5.

Exhibit 4.5-5
Visual Quality
Segment E
East Link Project

A wide variety of people (viewers) would see potential changes to the visual environment from the alternatives. Depending on the land uses in the project vicinity, viewers include commuters along major arterials, residents in nearby yards or buildings, park users and/or recreationists, and in commercial areas, workers or customers.

Viewers can be categorized as having low, average, or high sensitivity to changes in the viewed environment. Viewer sensitivity is strongly influenced by a viewer's activity, awareness of his or her surroundings, and amount of time spent looking at a view. People such as residents or regular park users who see a landscape multiple times for long periods of time would be aware of changes in the landscape. They would likely appreciate or be familiar with a landscape's aesthetic qualities and are assumed to have high viewer sensitivity. People who view a landscape infrequently, view it for short periods of time (often as they pass through it), or are not attentive to it due to focusing on other activities (such as driving or working) are often less sensitive to changes and are assumed to have low viewer sensitivity. Viewers with average viewer sensitivity include workers and customers who might expect a somewhat pleasant visual setting for the establishments they work in or frequent but are in the locations for purposes other than enjoying its scenery or visual quality.

The visual quality of an area can indicate how responsive an area's most sensitive viewers would likely be to changes in the visual environment. For example, viewers with high viewer sensitivity in areas that are categorized as having high visual quality would be expected to react more to changes in the visual environment than they would in areas that have medium or low visual quality.

The following subsections describe the visual character, visual quality, viewers, and viewer sensitivity for each project segment and for areas near the maintenance facilities.

4.5.2.1 Segment A

The Seattle portion of Segment A passes through mixed land use types—mainly industrial, transportation, and commercial—that have a generally utilitarian appearance and character. Much of the Seattle subarea of Segment A was categorized as having low visual quality. The exception is the hillside area west of the Interstate 90 (I-90) eastbound tunnel that contains residences and two parks (Judkins Park and Sam Smith Park); this area has a pleasant residential character that was categorized as being of medium visual quality. Some routes connecting to Segment A, including I-5 and I-90, have been identified by the City of Seattle as scenic routes or scenic routes with protected view rights-of-way. Subsection P (Public View Protection) of Seattle Municipal Code 25.05.675 (Specific environmental policies) states that it is the City's policy to protect public views of significant natural and built features, such as Mount Rainier, the downtown skyline, and historic landmarks, from these routes.

The visual quality of the tunneled portions of I-90 was categorized as low. Although the I-90 Floating Bridge and the East Channel Bridge offer memorable and vivid views for people using them, the structures themselves are utilitarian in appearance and are visual encroachments when viewed from Lake Washington or its shoreline. The section of I-90 that is the I-90 floating bridge has been categorized as medium. The portion of I-90 that passes through the Mercer Island retained cut is more attractive than typical freeways due to extensive landscaping and wall treatments. As a result, it was categorized as medium visual quality.

4.5.2.2 Segment B

The character and visual quality of south Bellevue is varied. All Segment B alternatives pass south and southeast of residences in the Enatai neighborhood. A few residences in this area have views to the south and southeast that include Lake Washington and adjacent areas, Mount Rainier, and I-90. Because of the presence and proximity of I-90, this viewshed has been categorized as having medium visual quality. With the exception noted below, most of Bellevue Way SE passes by single-family residential and mixed (i.e., small commercial, churches, and multifamily) land uses that have a pleasant, but not out-of-the-ordinary, appearance with medium visual quality.

Bellevue Way SE between I-90 and the South Bellevue Park-and-Ride has a medium visual quality. The portion of Bellevue Way SE between the north end of the South Bellevue Park-and-Ride and the intersection with 112th Avenue SE, however, was categorized as having high visual quality. The east side of Bellevue Way SE passes by Mercer Slough Nature Park, the Mercer Slough Blueberry Farm, and the Winters House and parking lot. Areas along both sides of the road contain considerable vegetation, particularly the slope west of the Bellevue Way SE. This vegetation screens views into much of Mercer Slough Nature Park from most of Bellevue Way SE. Bellevue Way north of the intersection with 112th Avenue SE is of medium visual quality with no distinctive visual attributes.

The portion of 112th Avenue SE between its intersection with Bellevue Way SE and SE 8th Street has a high visual quality. The areas adjacent to 112th Avenue SE have a "boulevardlike" appearance with well-maintained landscaping and memorable views of Mercer Slough West within the Mercer Slough Nature Park and otherwise suburban residences and the Bellefield Office Park.

The portion of the BNSF Alternative (B7) route that traverses Mercer Slough Nature Park passes over or near wetlands and streams. However, the I-90 bridge and associated structures are visual encroachments; therefore, overall visual quality was categorized as medium. Most views to the north from the I-90 Trail are blocked by vegetation, and most views to the south are blocked by I-90 freeway structures. Parts of the route that follows the former BNSF Railway corridor have a visual connection with the Mercer Slough Nature Park and/or pass through forested areas and have medium visual quality. Views along the portion of the route that is adjacent to I-405 and along 118th Avenue SE are visually dominated by I-405 and nearby large parking lots and were categorized as having low visual quality.

4.5.2.3 Segment C

Downtown Bellevue is an area in transition. Areas adjacent to Bellevue Way SE and 112th Avenue SE leading from Segment B into Downtown are likewise in transition. The areas are not particularly memorable, distinctive, or unique and, thus, have a medium visual quality category. The portion of Main Street that the alternatives would pass through includes low-rise retail and commercial buildings (some of which occupy residential buildings) and also has a medium visual quality category.

Much of Downtown Bellevue is continuing to evolve from areas of low-rise automobile-oriented commercial complexes to dense, large-scale, mixed-use mid- and high-rise buildings that have a highly urban character. A number of these types of developments exist or are being built along 108th and 110th Avenues NE and contribute to the high visual quality of the two streets. In addition to 108th and 110th Avenues NE, part of NE 12th Street has a high visual quality due to the presence of McCormick Park, Ashwood Park, the King County Bellevue Regional Library, and other new projects.

Outside of the Downtown Bellevue core, portions of the alternatives pass next to or over I-405. The routes east over I-405 pass through low-rise nonretail and retail commercial complexes with extensive parking areas are of low visual quality category. The alternative routes that parallel I-405 (or are within a block of it) to the west pass through areas along 114th Avenue SE (and NE) and 112th Avenue SE (and NE) that contain a variety of building types. These complexes are generally located away from the streets and are surrounded by parking lots. The visual presence of nearby I-405 is strong in most of these areas and has either low or medium visual quality.

4.5.2.4 Segment D

Much of Segment D passes through areas that contain a mixture of warehouses, industrial facilities, storage and parking lots, and "big-box" and other retail establishments set back from the street behind large areas of parking. As a result, the existing visual quality of most of Segment D is low. The area generally has a utilitarian appearance and character, although future land use plans that have been adopted by both the Cities of Bellevue and Redmond might improve the appearance by using more pedestrian-oriented urban development, street trees, and landscaping. There are a few areas of mature street trees that provide continuity and uniformity. As a result, a section of Segment D along 152nd Avenue NE in the Overlake area has been categorized as medium visual quality.

4.5.2.5 Segment E

The Downtown Redmond segment has a wide range of visual character and quality. The portion of the segment that follows SR 520 from Overlake Transit Center to the edge of the Sammamish River valley passes through a mixture of land uses (office, commercial, and residential). The visual character varies by location, but all areas are visually dominated by the presence of the freeway. As a result, areas along SR 520 were categorized as having low visual quality. Other areas in Segment E that were categorized as low visual quality include the business parks, industrial areas, developing areas along the former BNSF Railway, and industrial areas near Downtown Redmond. The portions of NE Redmond Way and Leary Way NE that pass over the Sammamish River have views of the river and parklands and serve as entries into parts of Downtown Redmond and were categorized as having high visual quality. The Sammamish River (and trail) also has high visual quality, as does the portion of SR 520 located between Marymoor Park and Redmond Town Center due to the views offered from it and its low horizontal presence on the landscape that is screened by areas of vegetation.

4.5.2.6 Maintenance Facilities

The maintenance facilities would be located in Segment D or E in or near areas that are currently industrial and utilitarian in use, appearance, and character. These areas were categorized as having low visual quality. The viewer sensitivity for these facilities was categorized as follows: commuters and others traveling on SR 520 or arterials (low), workers and customers (average), and residents (high).

4.5.3 Environmental Impacts

The assessment of potential impacts on the visual environment focused on the following:

1. Consistency with existing visual character
2. Changes in visual quality
3. Likely impact on viewers with high viewer sensitivity
4. Blockage of sensitive views with an emphasis placed on views that are identified by local jurisdictions as requiring protection
5. Creation of shadows
6. Light and glare

Regarding changes in visual quality (Item 2) impacts can be low, medium, or high. A high impact is defined as a reduction of the existing visual quality category by one or more categories. For example, if the visual quality category of an area is reduced from high to medium or changes from medium to low, the impact would be considered high. Impacts that are considered low or medium are not discussed but are noted in Appendix F4.5, Attachment 1.

The impact assessment emphasized areas where changes in the visual environment (Items 1 and 2) would be noticed by people with high viewer sensitivity (Item 3) and/or where sensitive views (Item 4) would be affected. For a view to be considered sensitive, it would need to be identified by a local jurisdiction (in comprehensive plans, ordinances, or other directives) as requiring protection or identified during scoping or agency review as requiring protection. The last two items, shading and light and glare, were assessed by examining engineering plans for likely impacts and examining the visual simulations of project features.

4.5.3.1 No Build Alternative

With the No Build Alternative, no new facilities would be constructed and no properties would be acquired that would change the existing visual environment. Under this alternative, the visual environment would remain essentially the same except as changes occur over time in individual properties. The No Build Alternative may contribute to lower density redevelopment, thereby maintaining lower profile commercial development and low to medium visual quality.

4.5.3.2 Impacts during Operation

The East Link Project would have visual impacts of varying degrees throughout the project vicinity, as discussed in the following subsections. Impacts were evaluated assuming that the project would incorporate the following measures used during project planning to avoid and minimize potential visual impacts:

- Selecting and/or modifying routes to avoid or reduce the need to acquire and clear new right-of-way. This measure has already been incorporated to a great degree in identifying route and station alternatives and includes using existing transportation corridors (arterial streets and highways, limited-access highways, and rail corridors), underground profiles, and retained-cut sections.
- Developing design criteria that guide project design issues such as architectural expression being a balanced approach of systemwide elements and contextual elements, systemwide signage for customer ease, and a systemwide art program. Interdisciplinary teams would develop designs, and the community would have opportunities to comment.
- During the design development process, subjecting station and facility designs to appropriate design reviews required by the cities in which they are located.
- Integrating facilities (particularly stations) with existing plans, including plans for redevelopment.
- Minimizing the elevation or height of elevated structures and stations to the extent allowed by required vertical clearances and design standards.
- Minimizing clearing for construction and operation.
- Planting appropriate vegetation within and adjoining the project right-of-way to replace existing street trees and other visually important vegetation that are removed for the project and/or to provide screening for sensitive visual environments and/or sensitive viewers.
- Maintaining remainder parcels and pursuing their redevelopment for land uses, such as residential, commercial, or open space uses, that are consistent with city plans.
- Using source shielding in exterior lighting at stations and ancillary facilities, such as maintenance bases and park-and-ride lots, so light sources (such as bulbs) are not directly visible from residential areas, streets, and highways, and

to limit spillover light and glare in residential areas.

Impacts Common to All Build Alternatives

All the build alternatives would change the visual environments in which they would be built. Construction and operation of the alternatives would require the removal of a variety of visual features such as buildings, street trees, landscaped areas, slopes (replaced with retaining walls), and parking lots. Project components would also be visible to varying degrees, which could change the visual environment in which the components are located. Some of the more potentially visible project components include elevated profiles and/or structures, stations, parking structures, sound walls or berms, and light rail vehicles. Table 4.5-1 lists the main components to be built for the East Link Project, describes their visual characteristics, discusses general types of measures that would be implemented to reduce potential visual impacts, and explains why the measures would be successful in reducing potential impacts.

Potential Impacts by Alternative

Most sections of the alternatives examined in this Final EIS would be consistent with their existing visual surroundings in terms of character and would not change the visual quality category of those surroundings. Table 4.5-2 summarizes areas where the existing visual quality categories would be lowered one or more categories despite the avoidance and minimization measures described in Table 4.5-1. Table 4.5-2 also indicates if there would be potential views blocked that have been identified by local jurisdictions as requiring protection. In addition, alternatives that might cause shading in areas that receive heavy pedestrian use are identified as areas where light and glare associated with the project might be an issue.

Most of the alternatives would not lower the visual quality categories of the areas through which they would pass. Exceptions in each segment are described in subsections below.

The following subsections discuss potential visual changes by segment and alternative. The discussion contains references to visual simulations that are provided in Appendix F4.5. Photographs in the appendix depict the existing views from the KOPs and visual simulations that display how the existing views would change with the alternatives.

Segment A

The overhead catenary support structures would be unique in parts of *Preferred Alternative A1*. The catenary lines on the floating bridge would be hung from a cross member supported by poles on one or both sides of the tracks; this would not likely impact visual quality along the I-90 corridor. The project and the catenary lines would be compatible in character with the D2 Roadway and I-90 (as shown in Appendix F4.5, Exhibit F4.5-1, Photo 1b). It would be consistent with the transportation-oriented character of the areas it would pass through and would reduce neither the visual quality category nor the viewer experience. The alternative and stations would not block view corridors identified by the City of Seattle or lower the visual quality categories of views from Judkins Park and Sam Smith Park in Seattle or from the Park on the Lid in Mercer Island, which overlook the trackway and stations. The two proposed stations, Rainier Avenue and Mercer Island (see Appendix F4.5, Exhibit F4.5-2, Photo 2b), would be consistent with the visual character of their surroundings. Their scale and design would help the project visually connect with adjacent neighborhoods.

Segment B

From Segment A, *Preferred 112th SE Modified Alternative (B2M)* would follow I-90 south of, and past, the Enatai neighborhood. The top of the elevated guideway, the overhead catenary system (OCS), and passing trains would be seen from some areas but would be consistent with the existing character of the view, which is dominated by the elevated I-90 (see Appendix F4.5, Exhibit F4.5-3, Photo 3b).

Preferred Alternative B2M would not change the view's existing medium visual quality category. *Preferred Alternative B2M* would approach the South Bellevue Park-and-Ride from the I-90 corridor as an elevated structure and would remove existing trees south of the park-and-ride lot (in the southwest corner of Mercer Slough Nature Park). The elevated station and parking structure would be noticed from areas such as Bellevue Way SE, parts of the Mercer Slough Nature Park, and residences west of Bellevue Way SE (to varying degrees) (see Appendix F4.5, Exhibit F4.5-4, Photo 4b).

The presence of station, parking structure, and sound walls along the western edge of the South Bellevue Park-and-Ride would change the appearance of the existing South Bellevue Park-and-Ride area. However, its facilities would be consistent with the transportation-oriented character of the existing park-and-ride lot and nearby I-90 structures and would not lower the existing medium visual quality category to low.

TABLE 4.5-1
Visual Characteristics of Project Components

Project Component	Visual Characteristics
Elevated guideways or structures (piers, straddlebents)[a]	These are often the most visible project components. The bottom parts of elevated guideways range between approximately 18 and 50 feet above grade. In some locations, elevated guideways (and their associated OCS components) can intrude on views, although they might not block them altogether. Elevated stations (and guideways, to a lesser extent) can create shadows that could have negative impacts in some areas under some conditions. However, stations and associated structures, such as elevators, escalators, and walkways, would be designed to be attractive architectural elements or features in the areas where they would be built and would add visual interest to the streetscapes near them.
At-grade trackways	At-grade trackways are generally located in or adjacent to existing streets. They would be designed to be compatible with the roadway or adjacent streetscape.
Overhead catenary system (OCS)	The OCS is a highly visible element from close viewing distances. OCS components (wires and poles) become less visible as viewing distances increase. The structures might intrude on views, but they do not block views due to their thin, cablelike profile and appearance.
Widened streets	Street widening can involve removing buildings, trees, and other vegetation and can require excavating hillsides or filling slopes. In some locations and situations, removing trees and other vegetation would be mitigated by replanting similar plants that over time mature enough to become similar in appearance with the vegetation that was removed.
Stations	Depending upon size, bulk, and whether they would be elevated or at-grade, stations can block views, cast shadows, or add built features to the landscape. Elevated stations are generally more visible than at-grade stations. Stations would be designed to be aesthetically and architecturally compatible with their surrounding areas. During station design, the stations would undergo appropriate design review as required by the cities in which they would be located.
Parking structures	Depending upon size and bulk, parking structures can block existing views. They can be designed or assigned criteria to match surrounding architecture types to help them aesthetically fit with their surroundings. Local landscape regulations would be followed to help parking structures visually and aesthetically better blend into the areas in which they would be located. Sound Transit would incorporate downward-directional lighting to minimize excess light spread on adjacent areas.
Parking lots	Parking lots result in additional hard surface, which are low in visual interest. Some jurisdictions require landscaping that can reduce the visual impact. Local parking lot and relevant landscape regulations would be followed to help parking lots visually and aesthetically better blend into the areas in which they would be located.
Lighting	If not properly designed and shielded, project-related lighting can create glare impacts, increase the level of ambient light in nearby areas, and/or increase skyglow, which can adversely affect nighttime views of the stars. This is true of both project operation and construction. Design-related measures such as shielding and altering light direction would be used where appropriate to reduce potential impacts.
Removed buildings	Removing existing buildings can improve or detract from visual settings, depending on building condition, style, scale, and color. Areas where buildings would be removed would contain project components and/or be revegetated to better blend in with nearby areas.
Removed vegetation	Removing vegetation can open up views that are nonexistent or, conversely, expose other nonaesthetic views, such as additional hard surfaces. When possible, Sound Transit would preserve existing vegetation, replant vegetation, replace trees, and screen to minimize effects of vegetation removal.
Retaining walls	Retaining walls often replace vegetated hillsides with hard materials, such as concrete, that might require surface design treatments to reduce impacts. Where appropriate, walls would be treated with surface design enhancements.
Sound walls	Sound walls are built of solid materials and placed adjacent to or attached to the light rail guideway. When this is not effective, sound walls might be constructed along property lines, sometimes replacing existing fences. The height and location of sound walls are not final in this EIS, and they are not depicted in visual simulations.
Maintenance facility	A maintenance facility can potentially block views or be viewed down upon from adjacent areas; however, the alternative sites for such a facility are located in areas that already have similar land uses, visual character, and structures. Maintenance facilities would be designed to be aesthetically compatible with the surrounding uses and would involve screening using fencing, walls, or vegetation to help them blend in with the areas in which they would be located. During facility design, the exterior of the maintenance facilities would undergo appropriate design review if required by the cities in which they would be located.
Retained cuts	These features would only be visible from nearby areas. Design guidelines and coordination with local jurisdictional design review would be applied to fencing and/or walls located at the top of the cut, which are the most visible components of this feature.
Traction power substations (TPSSs)	The TPSSs would be installed at about 2-mile intervals. They would be completely enclosed small metal buildings, measuring about 20 feet by 60 feet in size, with an additional 10 to 20 feet required around each unit. Where appropriate, they would be screened from public view with a wall or fence. The exterior walls or fences would be landscaped according to the landscape regulations of the jurisdictions in which the facilities are located.

[a] Piers are columns holding up the guideway; straddlebents are supports made of two columns and supporting a beam upon which the guideway sits.

TABLE 4.5-2
Summary of Changes to Visual Quality by Alternative

Alternative	Changes in Visual Quality Categories?	Sensitive View Blockage?	Shadows?
Segment A, Interstate 90			
Preferred Interstate 90 Alternative (A1)	**No**	No	No
Segment B, South Bellevue			
Preferred 112th SE Modified Alternative (B2M) to *Preferred Alternative C11A*	**No**	No	No
Preferred 112th SE Modified Alternative (B2M) to *Preferred Alternative C9T*	**No**	No	No
Bellevue Way Alternative (B1)	**Yes**—Removing vegetation and constructing retaining walls along the west side of Bellevue Way SE would lower visual quality from high to medium.	No	No
112th SE At-Grade Alternative (B2A)	**Yes**—Removing vegetation and constructing retaining walls along Bellevue Way SE would reduce high visual quality to medium for area between South Bellevue Station and 112th Avenue SE intersection. In addition, this alternative would be visible to varying degrees to approximately 15 to 20 residences on the hillside west of Bellevue Way SE.	No	No
112th SE Elevated Alternative (B2E)	**Yes**—Alternative B2E would have the same impacts on visual quality as Alternative B2A. The elevated alignment along Bellevue Way SE would be visible to varying degrees to approximately 15 to 20 residences on the hillside west of Bellevue Way SE, and it would intrude on eastern views from some of these residences. The elevated alignment would also be seen from some residences along the west side of 112th Avenue SE.	No	No
112th SE Bypass Alternative (B3)	**Yes**—Similar visual impacts as Alternative B2A would lower visual quality from high to medium along Bellevue Way SE between South Bellevue Station and intersection with 112th Avenue SE.	No	No
B3 - 114th Extension Design Option	**Yes**—Visual impacts would be the same as those for Alternative B3, but the design option portion would not contribute to any new visual impact.	No	No
BNSF Alternative (B7)	**No**	No	No
Segment C, Downtown Bellevue			
Preferred 108th NE At-Grade Alternative (C11A)	**No (for all connections from Segment B)**	No	No
Preferred 110th NE Tunnel Alternative (C9T)	**No (for all connections from Segment B)**	No	No
C9T - East Main Station Design Option	**No (only applicable for connection from Preferred Alternative *B2M*)**	No	No
Bellevue Way Tunnel Alternative (C1T)	**No (for all connections from Segment B)**	No	No
106th NE Tunnel Alternative (C2T)	**No (for all connections from Segment B)**	No	No
108th NE Tunnel Alternative (C3T)	**Yes**—Long-term construction impacts from removing mature trees and constructing the permanent presence of Alternative C3T in McCormick Park would lower visual quality from high to medium.	No	No
At-Grade Couplet Alternative (C4A)	**Yes**—Impacts would be similar to those for Alternative C3T, but a smaller portion of McCormick Park would be affected, and the route would be permanent feature in park, lowering visual quality from high to medium.	No	No
112th NE Elevated Alternative (C7E)	**No**	Yes - in limited areas	Yes – in limited areas

TABLE 4.5-2 CONTINUED
Summary of Changes to Visual Quality by Alternative

Alternative	Changes in Visual Quality Categories?	Sensitive View Blockage?	Shadows?
110th NE Elevated Alternative (C8E)	**Yes**—Elevated structures over 110th Avenue NE would be out of scale with pedestrian-oriented streetscape and would lower the existing high visual quality along 110th Avenue NE from high to medium. There would be the same impact as Alternatives C3T and C4A on McCormick Park from 110th Avenue NE to east end of park, lowering visual quality from high to medium.	Yes, possibly in one limited area	Yes, in limited areas
110th NE At-Grade Alternative (C9A)	**Yes -** Removing landscaped medians and vegetation along the east side of 112th Avenue SE and widening 112th Avenue SE farther north along with retained-fill transition structures on the elevated portion of the trackway and four straddle bents to cross 112th Avenue SE at Main Street would lower the medium visual quality to low.	No	No
114th NE Elevated Alternative (C14E)	**No**	Yes, possibly in one limited area	Yes, in limited areas
Segment D, Bel-Red/Overlake			
All Segment D alternatives and design options	**No**	No	No
Segment E, Downtown Redmond			
Preferred Marymoor Alternative (E2)	**No**	No	No
E2 - Redmond Transit Center Design Option	**No**		
Redmond Way Alternative (E1)	**Yes**—Removing hillside trees and the visual presence of a large-scale elevated horizontal element would temporarily lower visual quality from medium to low in limited areas until replanted trees attained sufficient size to screen views.	No	No
Leary Way Alternative (E4)	**Yes**—Removing the landscaped strip and mature street trees along portions of the south side of Leary Way would lower visual quality from high to medium.	No	No
Maintenance Facilities			
NE 116th Maintenance Facility (MF1)	**No**	No	No
BNSF Maintenance Facility (MF2)	**No**	No	No
SR 520 Maintenance Facility (MF3)	**No**	No	No
SE Redmond Maintenance Facility (MF5)	**No**	No	No

North of the South Bellevue Station, the alternative transitions from elevated to retained cut along the east of Bellevue Way SE. This would remove adjacent street trees and vegetation within Mercer Slough Nature Park. Removing the vegetation would change the existing appearance of this portion of Bellevue Way SE but would open views to the east towards Mercer Slough, the blueberry farm, and hills to the east for some nearby residents. A few residents west of Bellevue Way would have of views of *Preferred Alternative B2M's* OCS, but the guideway and trains would be blocked by nearby vegetation on the hillside west of Bellevue Way SE (see Appendix F4.5, Exhibit F4.5-5, Photo 5b).

North of the blueberry farm, the alignment profile enters a retained cut below the grade of the street and would be less visible to most viewers. Depending on adjacent vegetation and viewing location, viewers might see the catenaries and tops of the retaining walls/fencing and/or sound walls. Fencing above the retained-cut portion of the alternative would be required on top of a traffic barrier adjacent to the sidewalk. It would range from 6 feet to as high as 8 feet (when the guideway transitions into a retained cut) in height. In some locations sound walls would be installed. Because of the low profile provided by the retained cut and the retention of vegetation along the west side of Bellevue Way SE, *Preferred Alternative B2M* would not lower the existing high visual quality of this portion of Bellevue Way SE to enough to re-categorize it as medium.

Near and in front of the Winters House the retained cut would be covered with an approximately 170-foot-long lid. The lid in front of the Winters House would be landscaped (see Appendix F4.5, Exhibit F4.5-7, Photo 7b). North and south of the lid, a landscaping strip between the street and the sidewalk/retained cut barrier and fence would include street trees and plantings (see Appendix F4.5, Exhibit F4.5-7, Photo 7d). Although some mature vegetation, including larger trees near the house and parking area would be removed, this portion of Bellevue Way SE would maintain its high visual quality category.

Near the intersection of Bellevue Way SE and 112th Avenue SE, a number of deciduous trees would be removed within the construction right-of-way. However, vegetation (including trees) between the construction right-of-way and the intersection would be retained and would partially screen views of the retained cut profile. Because of the low retained cut profile, the alignment would not be readily seen from the intersection (see Appendix F4.5, Exhibit F4.5-8, Photo 8b). If necessary, Sound Transit would replant the area between the intersection and the alignment to enhance the visual buffer of *Preferred Alternative B2M* components. Removing vegetation would change the appearance of the intersection, but would not lower the area's high visual quality category to medium.

North of the intersection of Bellevue Way SE and 112th Avenue SE north to the Segment C boundary, *Preferred Alternative B2M* would have two variations when connecting to *Preferred Alternative C11A* or *C9T*. *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* transitions from the east side of 112th Avenue SE to the median of 112th Avenue SE at approximately SE 15th Street (see Appendix F4.5, Exhibit F4.5-9, Photo 9b). Landscaped medians along 112th Avenue SE north of this location would be removed (landscaped medians south of transition area would remain). People driving or walking along 112th Avenue SE would see the light rail track, catenaries, traffic gates at the rail crossing and a sound wall along the tracks or in front of the residential area west of 112th Avenue SE. Removing the landscaped medians would change the appearance of this part of 112th Avenue SE, but overall, the existing landscaped boulevard-like character of this part of 112th Avenue SE would be retained. The area's high visual quality would be retained.

Preferred Alternative B2M connecting to *Preferred Alternative C9T* remains on the east side of 112th Avenue SE in a retained cut or at-grade north to the SE 8th Station. The alignment would have a sound wall next to it along the east side of 112th Avenue SE. This alternative would remove some of the landscaped median between SE 15th and SE 8th Streets (see Appendix F4.5, Exhibit F4.5-9, Photo 9c). The remaining portions of the medians as well as adjacent vegetation would continue to contribute to the boulevard-like character of 112th Avenue SE. Although the presence of the alternative and the removed vegetation would be noticeable along this part of 112th Avenue SE, which would somewhat lower visual quality, the changes would not be enough to lower the existing visual quality category of high to medium.

The effects of *Preferred Alternative B2M* and its two variations would be viewed from parts of the Mercer Slough Nature Park, the Mercer Slough Nature Park Periphery Loop Trail (which in this area is the sidewalk adjacent to Bellevue Way SE and 112th Avenue SE), and the Water Trail. Removing street trees and trees located in the construction right-of-way east of Bellevue Way SE and 112th Avenue SE would be most noticeable from the loop trail and portions of the part of the Water Trail in Mercer Slough West. Trees along with the blackberry-covered slope between Mercer Slough and 112th Avenue SE would be removed and a retaining wall (supporting the at-grade alternative) built into the slope. The area between the trackway and the slough would be replanted with native and noninvasive vegetation. People using this portion of the Water Trail might have upward views of the catenaries and east face of the retaining wall, as they currently have upward views of the adjacent Bellefield Office Park, which is a midrise complex of office buildings, parking lots, and driveways that dominates views along this portion of the Water Trail.

The light rail would not be seen in most parts of the Mercer Slough Nature Park due the alternative's low profile and the presence of trees and large shrubs throughout much of the park. Removing large trees as a result of *Preferred Alternative B2M* would not be particularly noticed in most parts of the park due to the previously mentioned vegetation.

All of Segment B alternatives follow I-90 near the Enatai neighborhood and all but one; Alternative B7 curves away from I-90 to connect with Bellevue Way SE and the South Bellevue Park-and-Ride. Three of the Segment B alternatives—B2A, B2E, and B3—are elevated in this area, and Alternative B1 is at-grade. As with *Preferred Alternative B2M,* these facilities would be consistent with the transportation-oriented character of the I-90 corridor and its associated structures as well as the existing park-and-ride lot and would not lower the area's existing medium visual quality category to low. Because Alternative B1 remains at-grade with the I-90 off-ramp, it would be less visible to the Enatai residents than the other Segment B alternatives. Appendix F4.5, Exhibit F4.5-4, Photos 4c and 4d, depict the changes to the park-and-ride area from these alternatives when viewed from the residential area to the southwest.

In addition to *Preferred Alternative B2M*, Alternatives B2A, B2E, and B3 also travel along Bellevue Way SE and 112th Avenue SE. Unlike *Preferred Alternative B2M,* these alternatives would require varying heights and lengths of retaining wall along the elevated guideway, track, or along the west side of Bellevue Way SE and 112th Avenue SE, and they would remove vegetation along both sides of the roadways. Appendix F4.5, Exhibit F4.5-6, Photos 6b and 6c depict retaining walls along the west side of Bellevue Way associated with Alternatives B1, B2A, and B3 Appendix F4.5, Exhibit F4.5-6, Photo 6d depicts how Alternative B2E would appear from this location. The changes along the west side of Bellevue Way for Alternatives B1, B2A, B2E, and B3 would result in the visual quality category changing from high to medium. This change would likely be seen and noticed by sensitive viewers such as neighborhood residents, visitors to the Mercer Slough Blueberry Farm and the Winters House, and to a lesser degree, people recreating in the Mercer Slough Nature Park (although they would not see these changes from inside the park due to park vegetation that screens views of Bellevue Way SE from most trails). Removing trees and other vegetation along the west side of Bellevue Way SE would open up views to the east for some nearby hillside residents, although project features such as OCSs, guideways, and trains could be seen to varying degrees depending upon location and how much vegetation would be removed (see examples from one location in Appendix F4.5, Exhibit F4.5-5, Photo 5c through 5e).

Unlike *Preferred Alternative B2M*, none of the other Segment B alternatives traveling up Bellevue Way would change the context of the Winters House and its grounds when viewed from Bellevue Way SE. As mentioned previously, removing vegetation and constructing project elements would change the character of the west side Bellevue Way SE (see Appendix F4.5, Exhibit F4.5-6, Photos 6b and 6c). The following discusses the impacts of each of the other Segment B alternatives.

All of Alternative B1 is at-grade along Bellevue Way and, therefore, would not be visible or not very visible and from residences in the Enatai Neighborhood and west of Bellevue Way SE (see Appendix F4.5, Exhibit F4.5-5, Photo 5c). North of the 112th Avenue SE intersection, Alternative B1 would cause noticeable changes along Bellevue Way SE up to the Segment C boundary (112th Avenue SE). Although this alternative would widen the street, remove some vegetation and buildings, build retaining walls (primarily on the west side of the road) it would generally be consistent with the existing visual character of this part of Bellevue Way SE and would not change the existing medium visual quality category. Alternative B2A transitions from an elevated profile near the South Bellevue Station to at-grade and would be visible from approximately 15 to 20 residences west of Bellevue Way SE and could encroach on views to the east (see Appendix F4.5, Exhibit F4.5-5, Photo 5d). The alternative travels in the median of 112th Avenue SE and would remove the existing median vegetation. It would not, however, widen the road nor remove landscaping on either side of the road until just before the SE 8th Station (see Appendix F4.5, Exhibit F4.5-10, Photo 10b). These changes along Bellevue Way and the portion of 112th Avenue SE where the median would be removed would lower the visual quality from high to medium. North of SE 8th Street, an at-grade station built along 112th Avenue SE would widen the road near the station (but south of Surrey Downs Park in Segment C), remove numerous street trees, and increase the area of asphalt. Although these changes would alter the appearance and character of the intersection area and somewhat reduce its visual quality, Alternative B2A would not reduce visual quality enough to change the existing category from medium to low.

Alternative B2E would change the visual quality category (from high to medium) of the same portion of Bellevue Way SE that would be changed by Alternative B2A. The more extensive elevated profile of Alternative B2E would likely be noticed by more viewers than the at-grade alternatives. From several of the residences west of Bellevue Way SE, the project components would encroach on eastward views of the blueberry farm and Mercer Slough Nature Park (see Appendix F4.5, Exhibit F4.5-5, Photo 5e). North of SE 8th Street, an elevated station would result in a large-scale component adjacent to an office park and across the street from a residential area (see Appendix F4.5, Exhibit F4.5-10, Photo 10c), which would reduce the visual quality of the viewed landscape for residents but would not block views. The station would not lower the existing medium visual quality to low. A positive aspect of the elevated portions of this alternative would be that the project riders could enjoy elevated views of features such as parts of Mercer Slough and of the Mercer Slough Nature Park.

From Segment A to approximately 112th Avenue SE and SE 8th Street, the changes in visual quality associated with Alternative B3 would be the same as those described previously for Alternative B2A. North of the intersection of SE 8th Street and 112th Avenue SE, Alternative B3 leaves 112th Avenue SE and transitions from at-grade to an elevated structure (see Appendix F4.5, Exhibit F4.5-10, Photo 10d). Its route travels through an area that contains parking lots, office buildings, and an undeveloped open area, thus minimizing the need to remove large trees along 112th Avenue SE. The presence of the elevated profile would be consistent with the nearby structures, including I-405, and would not change the medium visual quality category of the area it would pass through.

The area that the B3 – 114th Extension Design Option passes through is a mixture of uses that includes office buildings, parking lots, an undeveloped area, and a hotel. From where the alignment parallels 114th Avenue SE, it then follows I-405. There is a lack of visual coherence along this route, and the existing visual quality is medium and low (along I-405). Further, this design option would not lower the existing visual quality of these areas.

Alternative B7 would not change the medium visual quality category along its route. The elevated structure crossing over Mercer Slough Nature Park would be noticeable to I-90 Trail users and would introduce a second major structural element into the view from the trail (see Appendix F4.5, Exhibit F4.5-12, Photo 12b). Some portions of the I-90 Trail would continue to be screened by vegetation immediately adjacent to the trail and by vegetation of varying distances north of the trail; this vegetation is very dense and blocks views north of it. Along portions of the trail where viewers would see the elevated structure, it would partially intrude on north views of park vegetation. Sensitive viewers (i.e., recreationists) would notice the light rail structure from portions of Mercer Slough Nature Park beyond the I-90 Trail (they would also see the existing I-90 structures). Due to the existing dominating presence of the I-90 bridge and its associated ramps along this portion of Alternative B7, as well as due to existing limited views to the north, the alternative's elevated structure would not decrease the area's existing medium visual quality category to low. This alternative would have sound walls along residential areas south of 118th Avenue SE, but it would also not decrease the medium visual quality category of the former BNSF Railway corridor in which it would be located to low. It would be consistent with the character of the portion of the alternative adjacent to 114th Avenue (SE and NE) and I-405 (see Appendix F4.5, Exhibit F4.5-13, Photo 13b).

Segment C

Preferred Alternative C11A from *Preferred Alternative B2M* would remove vegetation along the east side of 112th Avenue SE (including street trees north of SE 6th Street to Main Street). Removing residences and vegetation from Surrey Downs Park to Main Street on the west side of 112th Avenue NE would be noticeable to viewers from adjacent properties and to people travelling on 112th Avenue SE and would create an open space of approximately 50 feet (backed by sound walls) between the light rail and residences that would remain in place. This area would be landscaped and create a more open roadway appearance. The project and its landscaping would maintain the existing medium visual quality category (see Appendix F4.5, Exhibit F4.5-13, Photo 15b).

Most of the 108th Station is in a retained cut and would have a low profile when viewed from Main Street and from the back of the residences to the south of the station area. A landscaped buffer and transition area would be established between the residential neighborhood south of Main Street and the commercial areas and the city center to the north. This would be consistent with the *City of Bellevue Comprehensive Plan* (Policy S-DT-125) regarding transitions between downtown and the residential neighborhood to the southeast of downtown. The consistency with S-DT-125 would depend on coordination with the City of Bellevue for design and function of the linear space. Although *Preferred Alternative C11A* from *Preferred Alternative B2M* would somewhat change the visual appearance of this portion of Main Street, it would not lower the existing visual quality category of medium to low.

From the 108th Station to the at-grade Bellevue Transit Center Station, *Preferred Alternative C11A* would be consistent with the urban setting of 108th Avenue NE. Its right-of-way in the existing street would help it fit into the streetscape. *Preferred Alternative C11A* would change the appearance of 108th Avenue NE, but it would not lower its existing high visual quality category to medium.

A transition structure would be built along NE 6th Street between the Meydenbauer Convention Center and City Hall Plaza (see Exhibit F4.5-18, Photo18b). Sound Transit would collaborate with the City of Bellevue on aesthetic treatment of ornamental patterns or textures on walls of the transition structure and appropriate fencing. The presence of the transition and elevated structures would change the visual character of portions of NE 6th Street, but it would not change the existing medium visual quality category to low.

The portion of *Preferred Alternative C11A* that would cross over I-405 and connect with the Hospital Station would be consistent with the character of this area and would have little effect on visual quality. From the Hospital Station north to the Segment D boundary, *Preferred Alternative C11A* would not change the low visual quality along this part of the route.

Connections from Alternative B3, B3 – 114th Design Option, or B7 cross over 112th Avenue SE and then transition to retained fill before transitioning to at-grade. The elevated guideway and retained fill would be visible from 112th Avenue SE and Main Street, but the existing medium visual quality category would remain along these connections.

From the connection with *Preferred Alternative B2M*, the at-grade portion of *Preferred Alternative C9T* passes through the eastern edge of Surrey Downs Park and would remove vegetation. A SE 4th Street realignment through Surrey Downs Park would change the appearance of the portion of the park through which it passes (part of which is currently partially used for parking). The visual quality of this area would not be lowered from medium to low after construction and replanting.

North of the park, *Preferred Alternative C9T* is the same as *Preferred Alternative C11A* until approximately one block south of Main Street (see Appendix F4.5, Exhibit F4.5-15, Photo 15c). The area along the alternative route would provide opportunities for landscaping that could serve as a buffer between the trackway and nearby residences and function as a transition area between the neighborhood and the commercial and city center to the north. The transition structure and portal at 112th Avenue SE and Main Street would change the residential and small business character of the portion of its route, but it would maintain the area's existing medium visual quality.

With the C9T - East Main Station Design Option, an at-grade station would be located approximately 600 feet north of Surrey Downs Park on the west side of 112th Avenue SE. The area to the west of (and uphill of) the station would provide opportunities for landscaping and along with a sound wall could serve as a buffer between the station and nearby residences. The station would be compatible with the arterial and fronting commercial uses.

The portion of *Preferred Alternative C9T* located within the tunnel would not result in any visual impacts. *Preferred Alternative C9T* exits the tunnel along NE 6th Street (see Appendix F4.5, Exhibit F4.5-18, Photo 18c). After exiting the tunnel and continuing east over I-405 to the Hospital Station, the impacts would be similar to those identified for *Preferred Alternative C11A*, although the transition structure would begin at a lower elevation along NE 6th Street (from a tunnel portal) than the at-grade *Preferred Alternative C11A*.Although the *Preferred Alternatives C11A* and *C9T* would not change the visual quality categories of the areas through which they would pass, infringe on protected views, or cast shadows in heavily use pedestrian areas, the other Segment C alternatives would. The alternatives that would lower the existing visual quality category of part of their routes include Alternatives C3T, C4A, C8E, and C9A. Near sensitive receivers, sound walls would be necessary on the elevated guideway where Alternative C9A is elevated at Main Street and where C8E is elevated along 110th Avenue NE. Two elevated alternatives, C8E and C14E, could potentially intrude on sensitive views (Cascade Mountains) identified by the City of Bellevue. One alternative, C8E, would cast shadows in an area that receives heavy pedestrian traffic during part of the day. The following subsections describe the impacts associated with the Segment C alternatives.

The open portion of the retained cut and the tunnel portal portions of Alternative C1T would be noticeable from along Bellevue Way SE would not decrease the area's medium visual quality. The underground portion of Alternative C1T would have no impact on visual character or quality. After exiting the tunnel along NE 6th Street, this alternative would follow the route of *Preferred Alternative C9T* and would have the same impacts on the adjacent areas character and visual quality (see Appendix F4.5, Exhibit F4.5-18, Photo 18d).

Most of Alternative C2T would be underground and would have no impact on visual character or quality. The connection from Alternative B2A would require a retained cut along part of 112th Avenue SE that would not be visible in Surrey Downs. The retained cut would somewhat change the character of areas next to it but would not lower the existing medium visual quality to low.

The connector along Alternative B2E would widen the street, remove existing mature street trees that line parts of the street. Although the trees partially screen or soften views of parking lots along the east side of the street from residences on the west side, this would not lower the existing medium visual quality category to low. The elevated structure would cast shadows along 112th Avenue SE in the morning period (although less than the existing street trees do). The transition from elevated profile to tunnel along 112th Avenue SE turns west near Main Street before entering the tunnel (see Appendix F4.5, Exhibit F4.5-15, Photo 15d). This portion of Alternative C2T would not lower the existing medium visual quality category to low.

Alternative C2T exits the tunnel at a portal located on SE 6th Street, just south of the Meydenbauer Convention Center (see Appendix F4.5, Exhibit F4.5-18, Photo 18d). This alternative would have the same impacts as those described for *Preferred Alternative C9T* and would not lower the visual quality categories anywhere along the route. The other Alternative C2T connector from Alternative B7 or B3 follows 114th Avenue SE to the transition structure, and it would not change the existing freeway and parking lot dominated character of the route or its low visual quality category.

The impacts related to the Segment B connectors (Alternative B3, B2E, or B7) and for the tunnel described above for Alternative C2T would be the same for Alternative C3T. This alternative exits the tunnel at a portal located on along NE 12th Street and transitions to an elevated alignment over I-405 (see Appendix F4.5, Exhibit F4.5-21, Photo 21b). This alternative would have the same impacts as those described for *Preferred Alternative C9T* and would not permanently lower the visual quality categories anywhere along its route.

Alternative C3T would alter the appearance of McCormick Park between 108th and 112th Avenues NE because of tunnel construction, a permanent section of retained cut (flanked by sound walls on both sides), and a section of elevated structure. Alternative C3T would redesign and rebuild the park once the project is completed. Nearby residents, who have high viewer sensitivity, would be adversely affected by the project for several years until the redesigned park's vegetation (e.g., shrubs and groundcover) began to fill in; trees would take longer to adequately mature. Between the start of construction and several years after the new park is constructed, the visual quality category of the area near the park would be reduced from high to low. Within several years of completing the new park, plants would begin to fill in and visual quality would improve to medium. Visual quality could improve to high after 5 to 10 years, depending on the park design, growth of trees, and effectiveness of landscaping used to reduce the visual dominance of proposed project structures in the park.

Impacts related to the Segment B connectors (Alternative B3, B2E, or B7) described above for Alternative C2T would be the same with Alternative C4A, except these connectors are elevated across 112th Avenue NE and then transition to at-grade as they connect to the main portion of Alternative C4A. For Alternative C4A, the connector from Alternative B2A is the same as Alternative B2E; therefore, large trees would be impacted and an elevated profile would be introduced along 112th Avenue NE and sound walls would be built west of 112th Avenue SE and south of Main Street. Along 108th and 110th Avenues NE, the at-grade profile in the existing street right-of-way of the couplet would be consistent with the urban environment of Segment C and would not change the high visual quality category (see Exhibit F4.5-16, Photo 16b). The impacts from the portion of the route that passes along NE 12th Street would be similar to those described for Alternative C3T except that Alternative C4A remains at-grade as it enters McCormick Park rather than coming from a portal (see Appendix F4.5, Exhibit F4.5-21, Photo 21c) and a sound wall would be built along the north side of the at-grade alignment from 108th Avenue NE to 110th Avenue NE. The existing high visual quality of the area along NE 12th Street near McCormick Park would be reduced to medium, but as with Alternative C3T, it could be restored to high over time.

As with Alternative B3 and the Alternative B2A, B2E, or B7 connector from Segment B, Alternative C7E would not change visual quality categories between Segment B and Main Street. North of Main Street the elevated guideway structure would pass along 112th Avenue NE through areas categorized as having low or medium visual quality due to buildings being set back from the street behind extensive parking lots, and numerous views of, and access points to I-405. Alternative C7E would not change the existing visual quality categories along the route.

During sunny weather, the elevated structure would cast shadows along parts of 112th Avenue NE until early afternoon, when in some locations shadows would be cast across the street by the adjacent buildings. The intent of the urban design element of the *Bellevue Comprehensive Plan* is to reduce shadows in areas that receive heavy pedestrian use. This area is not a heavy pedestrian-traffic area; therefore, shadows from the overhead structure might not conflict under current conditions.

The Bellevue Transit Center Station with Alternative C7E near the intersection with NE 6th Street is connected to 110th Avenue NE by a raised pedestrian walkway (see Appendix F4.5, Exhibit F4.5-17, Photo 17b). The new structures would be visible in this general area, but they would be visually compatible with the area in terms of scale and design. The raised pedestrian walkway would provide a direct pedestrian connection between the station and Bellevue City Hall's plaza and nearby areas, so relatively few passengers would likely use the sidewalks along the section of 112th Avenue NE under the station and experience its shadows. The Alternative C7E elevated pedestrian walkway might intrude on views of some Cascade Mountain peaks from limited areas near 110th Avenue NE and NE 6th Street.

Farther north, along 112th Avenue NE, Alternative C7E passes the I-405/NE 8th Street interchange area (see Appendix F4.5, Exhibit F4.5-20, Photo 20b) while travelling along the east side of 112th Avenue SE. Alternative C7E passes office, mixed-use, and multifamily buildings, and the presence of the elevated structure would be noticeable to residents (who are sensitive viewers), particularly those on the second and third floors. Its presence, however, would not block visual access to the Cascade Mountains nor Mount Rainier due to relatively lower profile from adjacent residences; further, it would not reduce the medium visual quality of this part of 112th Avenue NE to low because the backdrop for these views are predominantly office buildings and I-405, another large transportation infrastructure.

The elevated structure and station associated with the Alternative B3 or B7 connector to Alternative C8E, including the portion located along NE 2nd Street, would be compatible with the character of I-405 and the existing development through which it passes, and it would not change the area's visual quality category. The visual quality of Alternative C8E's route would change along 110th Avenue NE near the Bellevue Transit Center and NE 6th Street due to the elevated profile (particularly the straddlebents [see notes of Table 4.5-1 for definition]) and elevated station. The elevated station would add a large-scale overhead visual element to an area that is pedestrian-oriented and receives heavy pedestrian use; it would not be consistent with the parklike character of Bellevue City Hall Plaza or the nearby streetscape (see Appendix F4.5, Exhibit F4.5-16, Photo 16c). The visual quality category of this portion of 110th Avenue NE would change from high to medium.

The elevated guideway and station would not block street-level views of Cascade Mountain peaks from along east-west running streets that cross 110th Avenue NE (the peaks that are currently visible and not blocked by buildings to the east and south would generally continue to be visible underneath the elevated elements). Shadows cast by the elevated station (and, to a lesser extent, the elevated guideway) during sunny weather might fall on sidewalks in portions of 110th Avenue NE that receive heavy pedestrian use. The shadows cast onto sidewalks by Alternative C8E would be noticed during times of the day when shadows cast by nearby buildings (particularly the highrise buildings on the west side of 110th Avenue NE) are not present, which along most sidewalks would be late morning to midafternoon. The elevated structures continue north along 110th Avenue NE past office and mixed-use buildings (see Appendix F4.5, Exhibit F4.19, Photo 19b).

The north portion of the Alternative C8E route passes through McCormick Park from 110th to 112th Avenue NE and would temporarily lower the area's visual quality. The impact of Alternative C8E would result primarily vegetation removal (particularly mature trees) and the presence of the elevated structure and straddlebent (see Appendix F4.5, Exhibit F4.5-21, Photo 21d) and would lower the visual quality in this area from high to medium until replanted vegetation became sufficiently mature.

Alternative C9A is similar to Alternative C4A in its connections from Segment B and the portion of the route along 110th Avenue NE. However, the connection from Alternative B2A begins at-grade, transitions to retained fill, and then becomes elevated in the center of 112th Avenue SE, which would widen the street to east and remove vegetation. Four straddlebents would be required to cross over 112th Avenue SE to Main Street. These changes would reduce the existing medium visual quality category of this part of 112th Avenue NE to low. Like *Preferred Alternative C11A*, Alternative C9A would maintain the medium visual quality category along Main Street and along 110th Street NE. This alternative would maintain the existing high visual quality category of 110th Avenue NE.

Alternative C14E parallels I-405 for much of its route, which would be consistent with the corridor's transportation infrastructure character. The elevated structure would not change the existing low visual quality category along this part of its route. The elevated profile would not block views of Cascade Mountain peaks from east-west running streets or areas along 108th Avenue NE (such as the City Hall

Plaza or the Bellevue Transit Center Station). If tent structures are used for the elevated station and pedestrian bridge that provide connection between 112th Avenue NE and the Bellevue Transit Center Station, then views of some Cascade Mountain peaks would be blocked from some viewing areas along 110th Avenue NE, NE 6th Street, and the Bellevue Transit Center (see Appendix F4.5, Exhibit F4.5-17, Photo 17c). The elevated pedestrian bridge and its associated tent structures would be large-scale elements but not out of scale with other nearby buildings or out of character with the general area. The elevated structure, station, and pedestrian bridge would not change the low visual quality category along 114th Avenue NE or the medium category along NE 6th Street. Therefore, relatively few pedestrians would experience its shadows.

Segment D

The City of Bellevue and City of Redmond have adopted plans and policies for areas through which *Preferred Alternative D2A* and the other Segment D alternatives would pass. The new plans and polices would, over time, increase pedestrian-oriented land uses and reflect improved urban design standards. The design of the stations would be subject to appropriate design review by the Cities of Bellevue and Redmond. Although the changes in land use and improved urban design standards will result in many areas becoming more attractive over time along the Segment D alternative, the baseline condition that is used to assess impacts is the existing condition. Because the existing condition is the baseline condition, elevated alternatives would not pass by any areas that currently receive heavy pedestrian use; therefore, shadows cast by them are not considered as potential impacts.

Preferred Alternative D2A would be compatible with the areas it would pass through and would not change visual quality categories of these areas, including the storage track location in the former BNSF Railway north of the Segment C/D break. This alternative would be a mix of at-grade, retained-cut, and elevated profiles. Most of the route passes through areas that are currently industrial, commercial (especially automobile-oriented retail), and transportation (the SR 520 corridor).

All of the stations would be designed to respond to the areas in which they would be built and would either improve the low visual quality of the areas where they would be built or would not change it. Both design options near the 120th Station would also be compatible with nearby areas. The at-grade 120th Station might be more visually compatible with the urban fabric than the retained-cut station plan, since the retained cut introduces a sense of a barrier. Appendix F4.5, Exhibit F4.5-25, Photo 25b contains a simulation of the Overlake Village Station that would be constructed alongside SR 520 with *Preferred Alternative D2A*. The station and alignment would be consistent with the transportation character of the portion of the route that would parallel SR 520 and would be a positive aesthetic addition to the area.

D2A - NE 24th Design Option passes through the Overlake Village in an area that has tree-lined streets. Near the Overlake Village Station, the alignment passes along the west side of 152nd Avenue NE (see Appendix F4.5, Exhibit F4.5-24, Photo 24b). The alignment and station would remove existing buildings and their associated vegetation, as well as street trees. The at-grade tracks and station would be consistent with the urban character of the area near the station and would not change the medium visual quality category of this area enough to reduce it to low.

All other Segment D alternatives would be compatible with the character of the areas through and by which they would pass. They pass through areas best described as either (or a combination of) industrial, commercial, transportation (along SR 520), automobile-oriented, or big-box store retail. The other Segment D alternatives would have varying impacts on visual character and quality, but none would lower existing visual quality categories from medium (the highest in this area) to low. The following highlights impacts along some of the routes of the other Segment D alternatives.

The elevated portion of NE 16th Elevated Alternative (D2E) would be noticed, but it would not be considered a visual encroachment and would be consistent with character of the areas it would pass by. Appendix F4.5, Exhibit F4.5-23, Photo 23b depicts a location along NE 24th Street where the Alternative D2E profile transitions from elevated to at-grade. Existing street trees would be removed and new ones planted. Although the elevated structure and at-grade profiles would be seen from this location (and other sections of NE 24th Street) and the removed street trees would be evident (until the replanted ones increased in size), the presence of Alternative D2E would not lower visual quality enough to reduce it from medium to low.

NE 20th Alternative (D3) travels along the median of NE 20th Street and enters a retained cut east of 140th Avenue NE and would widen either side of the road (see Appendix F4.5, Exhibit F4.5-22, Photo 22b). Existing sidewalks and adjacent landscaping would be removed. The appearance of NE 20th Street would change with Alternative D3 and the many parking lots that line the street that are currently somewhat screened by street trees and vegetation would be more clearly seen. The presence of this alternative in conjunction with the vegetation removal would lower the visual quality in this area (which is already categorized as low). Within 5 to 10 years, replanted vegetation would gain enough size to screen views and the overall visual quality of this area would improve.

Much of SR 520 Alternative (D5) parallels the I-405 corridor and would be consistent with the transportation character of the corridor; it would not change the low visual quality category of the corridor. Alternative D5 heads east from I-405 in a retained cut to 152nd Avenue NE, where it transitions to at-grade. Alternative D5 would be consistent with the character of the area through which it passes and would not change the medium visual quality category of the portion of 152nd Avenue NE it travels.

Any station from the last station in Segment C and east could potentially include a storage track. These would be primarily in line with the existing track configuration, except the storage track location proposed in the former BNSF Railway corridor associated with the *Preferred Alternative D2A* north of the Segment C and D break. All storage tracks in Segment D would be consistent with the visual analysis of that alternative. The storage track would reside behind existing industrial building outside of sensitive view areas and, therefore, would not lower the low visual quality category.

Segment E

Preferred Alternative E2 and the other Segment E alternatives parallel SR 520 between from the Overlake Transit Center to Sammamish River, where they diverge and the visual impacts would also vary from this point. The profiles are a combination of at-grade and retained cut and would be compatible with transportation infrastructure character of SR 520. The portions of the alternatives adjacent to SR 520 would not change the low visual quality category of the SR 520 corridor.

The portion of *Preferred Alternative E2* that would pass Marymoor Park would be sited adjacent but south of SR 520, and it would be barely visible from parts of Marymoor Park, (see Appendix F4.5, Exhibit F4.5-26, Photo 26b). *Preferred Alternative E2* would not lower the existing high visual quality category of the park. After leaving the Marymoor Park area, *Preferred Alternative E2* would be visually compatible in scale and urban character with the former BNSF Railway corridor. Both the *Preferred Alternative E2* and the E2 – Redmond Transit Center Design Option would be consistent with the character of areas in Redmond and might slightly improve the areas visual quality. Widening NE 161st Street for the design option would not lower the visual quality of the urban environment near the Redmond Transit Center.

The remaining Segment E Alternatives would have visual impacts. The Redmond Way Alternative (E1) travels west of West Lake Sammamish Parkway NE, is elevated, and passes through a heavily vegetated hillside located above a small commercial strip and below multifamily building complexes. This portion of the guideway may also include noise barriers. The primary impact of Alternative E1 on visual character and quality would be from strong visual presence of the elevated structure. (see Appendix F4.5, Exhibit F4.5-28, Photo 28b). Tree removal on this hillside would contribute to the visual impact (see Appendix F4.5, Exhibit F4.5-27, Photo 27b). Until replanted trees gained stature in 5 to 10 years, Alternative E1 would temporarily lower the existing visual quality of the section of West Lake Sammamish Parkway NE from medium to low in this area.

The portion of the elevated structure that parallels Redmond Way and crosses the Sammamish River would be seen from the Sammamish River Trail and from Luke McRedmond Landing Park (see Appendix F4.5, Exhibit F4.5-29, Photo 29b). This portion of the alternative would be similar to the bridge in character in terms of scale, form, materials, and color and would not lower the area's high visual quality category along Redmond Way, nor would it lower the visual quality of the former BNSF Railway corridor.

The Leary Way Alternative (E4) would remove mature street trees along the existing landscaped strip and the south side of Leary Way NE starting west of the Leary Way NE bridge over the Sammamish River and continuing east to near the former BNSF Railway (see Appendix F4.5, Exhibit F4.5-30, Photo 30b for the Sammamish River crossing simulation). Alternative E4 continues east along a portion of Leary Way NE that serves as a gateway into Downtown Redmond. The transition of elevated profile to at-grade and widening the tree canopy could lower the visual experience of the entryway and lower the visual quality classification of this part of Leary Way NE from high to medium. Sound Transit has prepared designs that show how proposed landscaping may minimize visual effects (see Appendix F4.5, Exhibit F4.5-31, Photo 31b). The portions of Alternative E4 route along the former BNSF Railway corridor and extending over the SR 520 interchange would be visually consistent with the area's character.

Maintenance Facilities
The maintenance facilities would not be out of character with the land uses around them. Most of the alternative maintenance facility sites are located in areas that are not visible to large numbers of people and have been categorized as having low visual quality. The maintenance facilities would have a perimeter fence and/or landscaping where necessary to screen views. The design of the facilities is subject to appropriate design reviews required by the cities where they would be located.

Maintenance facility alternatives located in the Bel-Red Subarea are compatible with adjacent land uses currently, but the City of Bellevue has adopted future land use plans that would limit future industrial uses in the area. The 116th Maintenance Facility (MF1) might require screening from the adjacent medical- and hospital-oriented uses but would not reduce visual quality. The BNSF (MF2) and the SR 520 (MF3) Maintenance Facilities would be visually consistent with the existing visual character and quality of areas near them. MF3 would be the most visible of the maintenance facilities, because it would be located between NE 20th Street and SR 520. However, as confirmed by several car trips along SR 520 to examine the visibility of MF3 from SR 520, most views from the freeway would be screened by vegetation and on-ramps (which would interrupt views towards the MF3 site from most eastbound lanes and all westbound lanes). MF3 would be seen from NE 20th Street and could be seen from some parts of Viewpoint Park and the Bridle Trails Neighborhood. These views would be considered in the MF3 design and landscaping, would be consistent with the character of the areas near it, and would not lower visual quality. The SE Redmond Maintenance Facility (MF5), which would be perhaps the most visually compatible of the maintenance facilities sites, is surrounded by light industrial land uses with no future plans of changing from these current land uses. The industrial park is already screened by commercial uses and mature growth.

4.5.3.3 Impacts during Construction

Constructing the East Link Project would result in temporary impacts on the visual environment. Construction would last in any given area approximately 2 to 5 years (tunnel construction generally takes longer than at-grade or elevated construction). Removing and demolishing existing buildings and implementing the changes in roads, natural vegetation, and landscaping would change the existing condition of the visual environment to varying degrees for varying amounts of time. Activities related to building the project would also have similarly temporary impacts on the visual environment and would include exposing and moving equipment and materials; exposing soils, glare, and lights associated with nighttime construction; storing construction materials; and making general visual changes to the viewed landscape during the project construction period. Staging areas as large as 6 acres would be required in Downtown Bellevue and would contain construction equipment, vehicles, and various activities; these areas would be screened from view where appropriate.

In addition, parks would be affected during construction. Similarly, in Segment B, the alternatives would affect Mercer Slough Nature Park. Some of the Segment C alternatives would affect Surrey Downs Park, the pocket parks, and McCormick Park during construction and require rebuilding affected park areas. All Segment E alternatives would affect trails and nearby parks to some extent. Nearby residents and park users would be adversely affected by the loss of the affected parks and project construction for approximately 3 to 5 years and, in some cases, longer for the restored parks' revegetation to mature. The severity of the impacts on the visual environment would depend upon the duration and the intensity of construction activities and their locations.

4.5.3.4 Consistency with Comprehensive Plans

As discussed throughout the visual analysis by alternative, Sound Transit's assessment of the East Link Project's consistency with visual-resource goals and policies of relevant local comprehensive plans found that with two exceptions, none of the general plans or subarea plans contain specific goals and polices for aesthetic or visual resources. However, most of the plans contain guidance relating to maintaining and improving the appearance of the physical environment. The two exceptions are as follows:

- *Bellevue Comprehensive Plan* urban design element that encourages new projects to be designed to avoid shadows and allow access to sunlight, particularly for areas that receive pedestrian use
- Section 20.25A.100.E.6 (View Preservation Corridor) of the City of Bellevue's *Downtown Core Design District Guidelines* that identifies view preservation corridors

Section F4.5.1 (Visual Consistency with Comprehensive Plans) of Appendix F4.5 (Visual Consistency and Key Observation Point Analysis) discusses the consistency of the *Preferred Alternative* (as well as all others) with the visual resource goals and policies of relevant local comprehensive plans and ordinances. Sound Transit will coordinate with the local jurisdictions to design the project consistent with pertinent policies, design guidelines, and regulations relative to visual and aesthetic resources.

The City of Bellevue developed the Downtown Core Design District to assist in implementing the *Downtown Subarea Comprehensive Plan* policies. Section 20.25A.100.E.6 of the guidelines concerns “View Preservation Corridors,” which would retain the opportunity for viewing “Lake Washington, the Seattle skyline, the Olympic Mountains and the Cascade Mountains from the major public open spaces and the major pedestrian corridor.” Sound Transit assessed Lake Washington views in Segment B and the Cascade Mountain views in Segment C. Two of the three major public spaces (106th and 110th Avenues NE) in the district would have Segment C alternatives passing through them and were assessed accordingly.

4.5.4 Potential Mitigation Measures

The following sections describe mitigation measures associated with the proposed project alternatives.

4.5.4.1 Mitigation for All Alternative Operational Impacts

As discussed at the beginning of Section 4.5.3.2, the project includes a number of measures to minimize visual impacts and build a visually compatible transit facility. No mitigation measures would be necessary for *Preferred Alternatives A1, B2M, C11A, C9T, D2A,* and *E2* because there would be no adverse visual quality impacts associated with these alternatives. Mitigation measures specific to identified locations of visual impact are listed below:

- **Bellevue Way SE between the South Bellevue Park-and-Ride and intersection with 112th Avenue SE.** This section of Bellevue Way SE would have impacts from Alternatives B1, B2A, B2E, and B3. The retaining walls would receive design treatments such as texture, patterns, color, and possible plantings. Vegetative screening would be provided by Sound Transit for residences where it would be practical and effective in screening views of the light rail.
- **112th Avenue SE median removal.** Removing the median in 112th Avenue SE north of Bellevue Way for Alternatives B2A and B3 would be mitigated with additional tree plantings east of 112th Avenue SE as practical.
- **112th Avenue SE straddlebents.** The retained fill and straddlebent for the connection from Alternative B2A to Alternative C9A along 112th Avenue SE would be designed to minimize bulk and reduce shadows as practical.
- **110th Avenue NE residential areas north of NE 8th Street.** Sound Transit would design Alternative C8E to minimize bulk and shadows and to improve pedestrian environment by enhancing visual aesthetics of the columns and elevated structure.
- **NE 12th Street near McCormick Park.** Alternatives C3T, C4T, and C8E would visually impacts this area. Sound Transit would develop plans for a redeveloped McCormick Park in conjunction with the City of Bellevue and with input from the community to reestablish a linear landscaped park along the north side of NE 12th Street and to screen project components from the park and nearby residences where appropriate.
- **Bellevue Transit Center Station Tents**. Sound Transit would work with the Cityof Bellevue to uphold the design of the station for Alternative C14E in conformance with the City’s policy to minimize view blockage of the Cascade Mountain peaks along 110th Avenue NE, NE 6th Street, and the Bellevue Transit Center, by altering or lowering the tent-type design.
- **NE Leary Way.** Alternative E4 would be located as close to Leary Way as practical to minimize clearing mature trees. Sound Transit would coordinate with the City of Redmond and provide landscaping between Leary Way and the light rail elevated guideway and at-grade trackway where there is space to do so (see Appendix F4.5, Exhibit F4.5-31, Photo 31b). This would help screen the light rail and reduce the visual impact to the NE Leary Way entry into Downtown Redmond.
- **West Lake Sammamish Parkway NE.** Sound Transit would minimize clearing during construction and, in consultation with the City of Redmond, plant trees and/or other vegetation along the edge of West Lake Sammamish Parkway NE for Alternative E1, as illustrated in Appendix F4.5, Exhibit F4.5-28, Photo 28b (this simulation does not depict the additional planting); this would help to screen views of the columns and structure from the street and from nearby condominiums and reduce the apparent bulk of this part of the elevated structure as illustrated in Appendix F4.5, Exhibit F4.5-27, Photo 27b (this simulation does not depict the additional planting).

4.5.4.2 Mitigation for Construction Impacts

During construction, Sound Transit would provide visual screening along the south side of Main Street for the 108th Station construction area for *Preferred Alternative C11A*, or along the south side of the tunnel portal construction area along Main Street for *Preferred Alternative C9T*. Visual screening would include construction of a solid barrier to screen ground-level views into the construction area from adjacent historic properties to the south. When possible, Sound Transit would preserve the existing vegetation. The decision whether to revegetate disturbed areas following construction would be determined based on future use of lands outside the trackway. Nighttime construction lighting would be shielded and directed downward to avoid light spillover onto adjacent sensitive uses.

4.6 Air Quality and Greenhouse Gases

4.6.1 Introduction to Resources and Regulatory Requirements

The East Link Project is located in King County in the Puget Sound Region and therefore falls within the jurisdiction of the Puget Sound Clean Air Agency (PSCAA) for local air quality regulation. Characterizing the existing air quality environment is essential in developing a baseline to assess how changes in vehicle traffic patterns related to the East Link Project might affect existing air pollutant concentration levels. Air quality is characterized in this section by discussing the applicable regulatory framework for the Puget Sound region, describing the existing attainment status with established air quality standards in the project vicinity for each regulated pollutant, and presenting existing air quality monitoring data that support the trend of how existing air pollution control measures improve air quality in the region.

On May 3, 2007, the State of Washington passed Senate Bill 6001, which aims to achieve 1990 greenhouse gas (GHG) levels by 2020, a 50 percent reduction below 1990 levels by 2030, and more by 2050. On October 6, 2010, the White House Council on Environmental Quality (CEQ) released Guidance on Federal Greenhouse Gas Accounting and Reporting that establishes government-wide requirements for measuring and reporting GHG emissions associated with federal agency operations. Currently, the Washington State Department of Ecology (Ecology) has prepared a working paper to assist in applying the State Environmental Policy Act (SEPA) to proposals that will result in GHG emissions or that may be vulnerable to the impacts of those emissions: climate change. A final draft is expected to be released in 2011. Although GHG emissions are federally regulated for large industrial sources, guidance on how to address GHG emissions in environmental documents is currently being developed.

4.6.2 Affected Environment

4.6.2.1 Regulatory Agencies and Requirements

Air quality in the Puget Sound region is regulated and enforced by federal, state, and local agencies—the U. S. Environmental Protection Agency (EPA), Ecology, and PSCAA—each with its own role in regulating air quality. Following the requirements of the federal Clean Air Act (CAA), EPA sets the criteria for National Ambient Air Quality Standards (NAAQS) and conformity requirements and has oversight authority over both PSCAA and Ecology. Ecology strives to improve air quality throughout the state by overseeing the development and conformity of the State Implementation Plan (SIP), which is the state's plan for meeting and maintaining NAAQS. The PSCAA has local authority for setting regulations and permitting of stationary air pollutant sources and construction emissions.

EPA's NAAQS sets limits on concentration levels of certain pollutants, commonly referred to as the "criteria pollutants." The six criteria pollutants are carbon monoxide (CO), lead, nitrogen dioxide (NO_2), particulate matter less than 10 microns (PM_{10}) and 2.5 microns ($PM_{2.5}$) in diameter, ozone (O_3), and sulfur dioxide (SO_2) (EPA, 2007b). The NAAQS for these criteria pollutants are separated into two standard categories: the Primary and the Secondary standards (40 Code of Federal Regulations [CFR] 50). The Primary standards were created to protect public health; the secondary pollutant standards were established to protect public welfare and the environment.

Table 4.6-1 displays the Primary and Secondary NAAQS for these six criteria pollutants. Ecology and PSCAA have authority to adopt more stringent standards, although many of the state and local standards are equivalent to the federal mandate.

4.6.2.2 Conformity Requirements

The CAA amendment of 1990 and State of Washington regulation require all transportation projects located in air quality maintenance and nonattainment areas in Washington to follow conformity requirements promulgated in their respective regulations (40 CFR Part 93 and Washington Administrative Code [WAC] 173-420) and to conform to the SIP. By conforming to the SIP, the proponent demonstrates that the transportation project will not add any new air quality violations to the area, will not worsen the current violations, and/or will not delay the attainment goals of the NAAQS. The state regulation requires Ecology and the Washington State Department of Transportation (WSDOT) to develop air quality-based criteria for transportation projects to demonstrate conformity to the SIP, for attaining and maintaining the NAAQS, and for meeting all standards of the CAA.

TABLE 4.6-1
Ambient Air Quality Standards by Government Jurisdiction

Pollutant	National		Washington State	Puget Sound Region
	Primary	Secondary		
Nitrogen Dioxide (NO_2)				
Annual Average	0.053 ppm	0.053 ppm	0.05 ppm	0.05 ppm
Carbon Monoxide (CO)				
1-hour average	35.0 ppm[a]	NS	35.0 ppm	35.0 ppm
8-hour average	9.0 ppm[a]	NS	9.0 ppm	9.0 ppm
Ozone (O_3)				
8-hour average (1997 standard)	0.08 ppm[b]	0.08 ppm[b]	NS	NS
8-hour average (2008 standard)	0.075 ppm[b1]	0.075 ppm[b1]	NS	NS
Lead				
Maximum arithmetic mean (averaged over a calendar quarter)	1.5 μg/m^3	1.5 μg/m^3	NS	1.5 μg/m[c]
Sulfur Dioxide (SO_2)				
1-hour average	NS	NS	0.40 ppm	0.40 ppm
3-hour average	NS	0.5 ppm	NS	NS
24-hour average	0.14 ppm[a]	NS	0.10 ppm	0.10 ppm
Annual arithmetic average	0.03 ppm	NS	0.02 ppm	0.02 ppm
Particulate Matter (PM_{10})				
24-hour average	150 μg/m^3	150 μg/m^3(c)	150 μg/m^3	150.0 μg/m^3
Annual arithmetic average	Revoked[d]	Revoked[d]	50 μg/m^3	50.0 μg/m^3
Particulate Matter ($PM_{2.5}$)				
24-hour average	35 μg/m^3(e)	35 μg/m^3(e)	NS	NS
Annual arithmetic average	15.0 μg/m^3(f)	15 μg/m^3(f)	NS	NS
Particulate Matter (TSP)				
24-hour average	NS	NS	150 μg/m^3	NS
Annual geometric average	NS	NS	60 μg/m^3	NS

Source: EPA, June 2010, Washington State Dept of Ecology**, 2010**

[a] Not to be exceeded more than once per year.

[b] To attain this standard, the 3-year average of the fourth-highest daily maximum 8-hour average ozone concentrations measured at each monitor station within an area over each year must not exceed 0.08 ppm.

[b1] The 1997 standard—and the implementation rules for that standard—will remain in place for implementation purposes as EPA undertakes rulemaking to address the transition from the 1997 ozone standard to the 2008 ozone standard. EPA is in the process of reconsidering these standards (set in March 2008).

[c] Not to be exceeded more than once per year on average over 3 years.

[d] Due to a lack of evidence linking health problems to long-term exposure to coarse particle pollution, the agency revoked the annual PM_{10} standard in 2006 (effective December 17, 2006).

[e] To attain this standard, the 3-year average of the 98th percentile of 24-hour concentrations at each population-oriented monitor station within an area must not exceed 35 μg/m^3 (effective December 17, 2006).

[f] To attain this standard, the 3-year average of the weighted annual mean $PM_{2.5}$ concentrations from single or multiple community-oriented monitor station must not exceed 15.0 μg/m^3.

ppm = parts per million

μg/m^3 = microgram per cubic meter

NS = no standard established

TSP = total suspended particulates

The East Link Project is located in the Puget Sound region, which is a maintenance area for CO, with a portion of the project also located in the Duwamish PM_{10} maintenance area. The area is in attainment for all other criteria pollutants.

The project is required to meet conformity requirements both on a regional and project level.

Regional conformity is demonstrated if the project is included in a conforming regional transportation plan (RTP) and a regional transportation improvement program (RTIP). Project-level conformity is demonstrated when three conditions are met:

- The project does not increase the severity or frequency of existing exceedances of the CO and PM_{10} standards.
- The project does not cause a new exceedance of the CO and PM_{10} standards.
- The project does not delay the timely attainment of the CO and PM_{10} standards.

4.6.2.3 Climate and Air Quality

The East Link Project is in the Puget Sound Lowland, which comprises a narrow strip of land along the western side of Puget Sound extending from the Strait of Juan de Fuca in the north to the southern cities of Centralia and Chehalis, and a somewhat wider strip along the eastern side of Puget Sound extending north to the Canadian border. Buffered by the Olympic and Cascade mountain ranges and Puget Sound, the Puget Sound Lowland has a relatively mild, marine climate with cool summers and mild, wet, and cloudy winters.

The prevailing wind direction in the summer is from the north or northwest. The average wind velocity is less than 10 miles per hour (mph). Persistent high-pressure cells often dominate summer weather, creating stagnant air conditions. This weather pattern sometimes contributes to the formation of photochemical smog.

During the winter wet season, the prevailing wind direction is south or southwest. Cold air occasionally flows southward from the interior of Canada through the Fraser River canyon into the Puget Sound Lowland. In the fall and winter, severe storms can produce strong winds that cross the state from the southwest.

Although the Puget Sound Lowland area is the most densely populated and industrialized area in Washington, there is sufficient wind most of the year to disperse air pollutants released into the atmosphere. Air pollution is usually most noticeable in the late fall and winter, under conditions of clear skies, light wind, and a sharp temperature inversion. Temperature inversions occur when cold air is trapped under warm air, preventing vertical mixing in the atmosphere. Inversions can last several days and can prevent pollutants from being dispersed by the wind. Inversions are most likely to occur during the months of October to January. If poor dispersion persists for more than 24 hours, the PSCAA can declare an “air pollution episode” or local “impaired air quality.”

4.6.2.4 Pollutants of Concern

Air quality is affected by pollutants that are generated by both natural and manmade sources. In general, the largest manmade contributors to air emissions are transportation vehicles and power-generating equipment, both of which typically burn fossil fuels. The main criteria pollutants of interest for transportation projects are CO, PM, O_3 and the O_3 precursors, volatile organic compounds (VOCs), and oxides of nitrogen (NO_x). Both federal and state standards regulate these pollutants, along with two other criteria pollutants, SO_2 and lead. However, since the Puget Sound region is in attainment and not a maintenance area for NOx, lead, and SO_2, these pollutants are not addressed in this analysis.

The largest contributors of pollution related to transportation projects are motor vehicles. The main pollutants emitted from motor vehicles are CO, particulates, O_3, GHGs, and air toxic pollutants. Motor vehicles also emit pollutants that contribute to the formation of ground-level ozone. This section discusses the main pollutants of concern and their impact on public health and the environment.

Carbon Monoxide

In assessing the localized air quality impacts of transportation projects, CO is the main pollutant of concern. CO is a colorless, odorless, and tasteless gas that results from the incomplete combustion of fuel. CO is ingested into the body by breathing. In low concentrations, CO can cause fatigue in healthy people and chest pain in people with heart conditions. At higher concentrations, CO can cause dizziness, impaired vision and coordination, confusion, headaches, and nausea. In exceptionally high concentrations, CO can be fatal.

The major source of CO is vehicular traffic, along with industry, wood stoves, and slash burns. For urban areas, motor vehicle internal combustion engines are the principal sources of CO that cause ambient air quality levels to exceed the NAAQS. CO concentration increases occur during vehicle cold-starts and winter months when meteorological conditions favor the build-up of directly emitted contaminants. CO is a pollutant whose impact is usually localized, with the highest ambient concentrations of CO occurring near congested roadways and intersections.

Particulate Matter

Particulate matter consists of small particles of dirt, soot, metals, and organic matter. PM of 10 microns in diameter and smaller pose the greatest health problems because it can bypass the natural filtration systems of the nose and throat and enter deep into the lungs, heart, and even the bloodstream, which can cause difficulty with breathing, aggravation of asthma, irregular heartbeat, nonfatal heart attacks, and death in people with heart or lung problems. Due to the size of PM_{10} and $PM_{2.5}$, the wind easily picks up the particles and transports them over long distances to settle on either the ground or water. PM that lands on the ground has the potential to deplete nutrients in the soil, damage sensitive crops, and change the structure of the ecosystem. PM that lands on water can change the acidity in lakes and streams and change the nutrient balance in coastal waters and large river basins. Major sources of PM are construction activity, smokestacks, fires, power plants, and automobiles.

The EPA has set standards for two different size categories of PM. The first standard set is for PM_{10}: particles that are larger than 2.5 microns and smaller than 10 microns in size. These particles are considered "inhalable course particles" and can be found near roadways and dusty industries. The second set of standards is for $PM_{2.5}$: particles that measure 2.5 microns in size and smaller. These particles are called "fine particles" and can usually be found in smoke and haze. These particles are normally directly emitted from forest fires or they can be formed from gases emitted from power plants and automobiles.

Ozone

Normally, O_3 is not emitted directly into the air; however, at ground level, NO_x and VOCs react under the presence of sunlight to form O_3. Emissions from industrial and electric facilities, motor vehicle exhaust, gasoline vapors, and chemical solvents are major sources of NO_x and VOCs.

Ground-level and stratosphere-level O_3 share the same chemical structure; however, their effects differ greatly due to their positions in the atmosphere. Ground-level O_3 has adverse effects due to its potential impacts on human health, while stratospheric ozone has a protective effect by shielding the earth's surface from harmful radiation. When O_3 is inhaled, it can cause a variety of health problems, such as chest pain, coughing, throat irritation, and congestion. The effects can potentially worsen to bronchitis, emphysema, and asthma, reducing lung function and inflaming the linings of the lungs. Repeated exposure can eventually lead to permanent scarring of the lung tissue. Not only does O_3 cause negative human health effects, but it also causes damage to the environment. O_3 can cause sensitive plants to be more susceptible to certain diseases, insects, and other pollutants, which can lead to reduced crop yields, forest growth, and potentially to impacts on species diversity in ecosystems.

O_3 is also the primary element of smog. Sunlight and hot weather are the main causes of the formation of ground-level O_3. As a result, O_3 is referred to as a summertime air pollutant. Many urban areas tend to have high levels of O_3, although even rural areas are subject to increased O_3 levels because the wind can carry O_3 and the pollutants that form O_3 miles away from their original sources.

Climate Change and Greenhouse Gases

Global climate change refers to changes in average climatic conditions on Earth as a whole, including changes in temperature, wind patterns, precipitation, and storms. Global temperatures are moderated by naturally occurring atmospheric gases, including water vapor, carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), which are known as GHGs. These gases allow solar radiation (sunlight) into the Earth's atmosphere, but prevent radiative heat from escaping, thus warming the Earth's atmosphere. Gases that trap heat in the atmosphere are often called GHGs, analogous to a greenhouse. GHGs are emitted by both natural processes and human activities. The accumulation of GHGs in the atmosphere regulates the Earth's temperature. Without these naturally occurring GHGs, the Earth's temperature would be about 61° Fahrenheit cooler (California EPA, 2006) than it is today. Emissions from human activities, such as electricity production and vehicle use, have elevated the concentration of these gases in the atmosphere, leading to even higher ambient temperatures.

Global warming is a regional and ultimately a worldwide concern. Historical records indicate that global climate changes have occurred in the past due to natural phenomena. However, data indicate that the current global conditions differ from past climate changes in rate and magnitude. Since GHG effects are experienced on a global scale, it is impossible to discuss direct effects of a single development project with future specific climate change.

CO_2 is the most abundant GHG and the primary GHG pollutant emitted by the combustion of fossil fuels. Although they are released by natural processes, burning of fossil fuels by humans produces substantial amounts of these gases. Changes in global CO_2 emissions from fossil fuel combustion are influenced by many long-term and short-term factors, including population and economic growth, energy price fluctuations, technological changes, and seasonal temperatures.

In contrast to most criteria pollutants, emissions of GHGs have been rising from many sources (i.e., industrial, residential, commercial, and transportation). Two of the largest contributors to GHG emissions in the United States are transportation and energy production, although residences, offices, and industries contribute as well. In 2003, it was found that combustion of transportation fuels, the largest source of CO_2, contributed 28 percent of the U.S. GHG emissions. In Washington, the transportation sector accounts for roughly 47 percent of GHG emissions, measured in million metric tons of carbon dioxide ($MMTCO_2e$) (Exhibit 4.6-1). One reason that transportation makes up such a large portion of GHG emissions is that in Washington there is a larger percentage of hydroelectric power than in many other states, so GHG use for electricity production is less than the national average, thereby decreasing the state's total GHGs. The decrease in total GHGs increases the percentage of GHGs from transportation.

The state legislature and mayors of the impacted cities intend to address transportation-related GHGs by reducing their communities' GHG emissions by certain percentages by 2020. GHG emissions from transportation sources are directly related to energy consumption and primarily result from the combustion of fossil fuels in vehicles. The GHG emissions associated with electrical transportation vary widely, depending on the source of electricity. For example hydro-electric generation produces much less GHG emissions than coal plants do. Generally, combusting fuel at a power plant to produce electricity is more efficient than fuel combustion in vehicles. To reduce GHG emissions from transportation sources, effective planning must incorporate modes of transport that use less energy per person per mile traveled and/or use energy derived from fuels that have low carbon content per unit of energy. For example, by changing bus fleets from diesel to natural gas, GHG emissions can be reduced through the use of a low carbon-intensity fuel, and they can be further reduced by increasing regional transit ridership, which uses less energy per person per mile traveled than single-occupant vehicles.

High-capacity transit is integral to fostering the urban villages and growth patterns encouraged by the Washington State Growth Management Act (GMA) and *VISION 2040* (PSRC, 2008). Transit provides an alternative to cars and therefore to the dependence on burning fossil fuels, and it reduces individual vehicle miles estimates. Across the country, studies show how rail-based transit is spurring high-quality, dense transit-oriented development (Cervero, 2008). Focusing growth in "urban centers"—and the density and mix of land uses it implies—is intended to enable residents to live near jobs and other urban activities, to

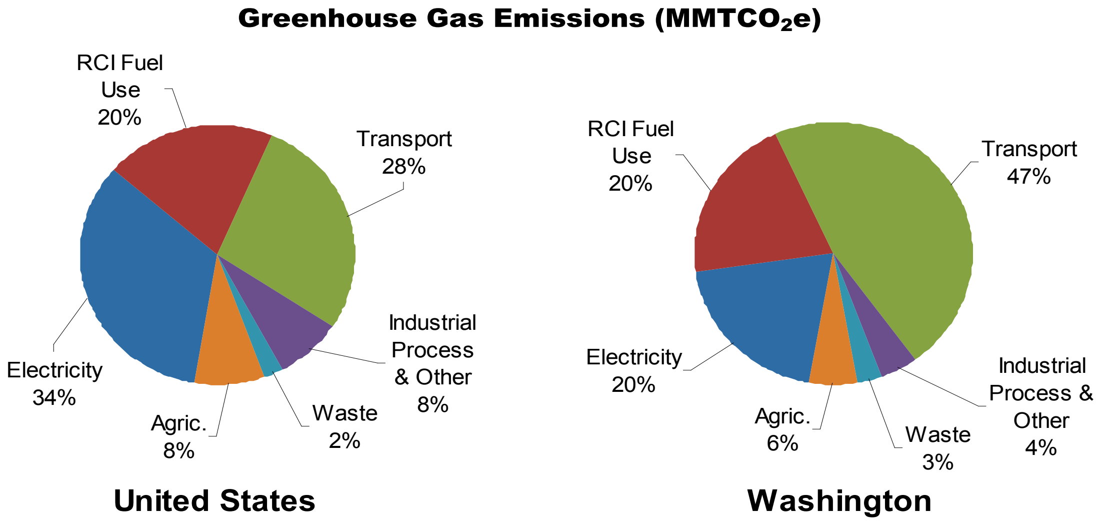

EXHIBIT 4.6-1
Comparison of National and Washington Greenhouse Gas Emissions
Source: Ecology, 2008
(RCI = Residential, Commercial, and Industrial)

help strengthen existing communities, and to promote bicycling, walking, and transit use. The benefits of more walkable communities and convenient alternatives to single-occupant vehicles are well-understood but not easily quantified.

Air Toxic Pollutants

Other pollutants known to cause cancer or other serious health effects are called air toxics. Ecology began monitoring air toxics at the Seattle Beacon Hill site in 2000. In addition to regulating the criteria pollutants, the CAA identifies 188 air toxics, also known as hazardous air pollutants. EPA assessed this expansive toxics list and identified a group of 21 air toxics as mobile source air toxics (MSATs), which are set forth in an EPA final rule, Control of Emissions of Hazardous Air Pollutants from Mobile Sources (66 *Federal Register* [FR] 17235). The EPA then extracted a subset of this list of 21, which it labels the seven priority MSATs: benzene, formaldehyde, diesel particulate matter/diesel exhaust organic gases, acrolein, naphthalene, polycyclic organic matter, and 1,3-butadiene. Exposure to these pollutants for long durations and sufficient concentrations increases the chances of cancer or other serious health effects, including damage to the immune system, neurological problems, and reproductive, developmental, respiratory, and other serious health problems.

The 2004 PSCAA inventory shows that on-road vehicles continue to be the greatest contributors to both criteria pollutant and air toxics emissions in the Puget Sound airshed (PSCAA, 2007). Transportation projects with high potential for MSAT impacts are required to perform project-level MSAT analysis.

4.6.2.5 Air Quality Monitoring and Trends

An area is designated a “nonattainment area” when measured concentrations exceed the NAAQS for a particular pollutant. The area remains a nonattainment area for that particular pollutant until concentrations are in compliance with the NAAQS. Only after measured concentrations have fallen below the NAAQS can the state apply for redesignation to attainment, and it must then submit a 10-year plan for continuing to meet and maintain air quality standards that follow the CAA. During this 10-year period, the area is designated as a “maintenance area.” The Puget Sound region, including King County, is currently classified as a maintenance area for CO. The 1-hour O_3 standard was revoked by EPA on June 15, 2005 (40 CFR 50.9(6) and 70 FR 44470). The area currently meets the 8-hour standard; therefore, the maintenance designation for O_3 no longer applies in the Puget Sound region. The approval for PM_{10} in the Seattle Duwamish area came in December 2000 and was redesignated as a maintenance area on March 13, 2002.

The PSCAA monitors criteria air pollutant concentrations at eight facilities in King County, but there are no facilities monitoring NO_2, SO_2, or lead near the project vicinity. CO concentrations are measured at two locations; four locations are currently monitoring O_3 concentrations; three locations are monitoring $PM_{2.5}$ concentrations; and two locations are measuring PM_{10} concentrations. One monitoring station located near Beacon Hill and near the project vicinity measures concentrations of all four pollutants: CO, PM_{10}, $PM_{2.5}$, and O_3. Table 4.6-2 displays the last 3 years of monitoring data to show that the air pollutant concentration trends for these pollutants remain below the NAAQS.

Emission projections and ongoing monitoring throughout the Central Puget Sound region indicate that the ambient air pollution concentrations for CO and PM_{10} have been decreasing over the past decade. Measured O_3 concentrations, in contrast, have remained fairly static. The decline of CO is due primarily to improvements made to emission controls on motor vehicles and the retirement of older, higher-polluting vehicles. However, PSRC estimates that by 2040, the Puget Sound region population will grow by 1.7 million people, increasing 52 percent, to reach a population of 5 million people (PSRC, 2009).

The highest population increase is estimated to be in King County. Estimates like this indicate that CO, PM_{10}, and O_3 emissions will increase , which could lead to future violations. With half of the region’s GHG emissions coming from transportation activities, PSRC’s *VISION 2040* calls for developing a more sustainable transportation system. The transportation policies call for reducing pollution through cleaner cars, buses, and trucks; cleaner fuels; and fewer vehicle miles traveled. Future mobility needs must consider alternatives to fossil fuels, new transportation technologies, and more alternatives to driving alone. If none of these methods succeed in maintaining emissions, more stringent standards might be needed for the central Puget Sound region to stay in attainment for all criteria pollutants.

Air toxic pollutant emissions are also of concern because of the projected growth in vehicle miles traveled (VMT). EPA has been able to reduce benzene, toluene, and other air toxics emissions from mobile sources by placing stringent standards on tailpipe emissions and requiring the use of reformulated gasoline. Future regulations on fuel and motor

TABLE 4.6-2
Ambient Air Quality Monitoring Data at Beacon Hill in Seattle

Pollutant	2006 Maximum Concentration	2007 Maximum Concentration	2008 Maximum Concentration	NAAQS/PSCAA Standard[a]

ppm	parts per million
µg/m^3	micrograms per cubic meter
NS	no standard

vehicles are expected to reduce air pollutant emissions from 1990 by more than 75 percent by 2020 (EPA, 2007a).

4.6.3 Air Quality Impacts

Operational impacts are assessed at both the regional and local scale of the project.

4.6.3.1 Regional Operational Impacts

Regional operational impacts were assessed by calculating tailpipe emissions for all criteria and toxic air pollutants for the East Link Project using the annual traffic forecast for the full-length, low-ridership, and high-ridership projects for 2020 and 2030. These two conditions represent the full range of potential operational impacts for the project. The year 2020 was chosen as the project's initial forecast year and is the estimated year of opening. The year 2030 represents the future forecast year that is consistent with the regional transportation plan adopted when the analysis began (PSRC, 2001).

Criteria Pollutant Emissions

The tailpipe emission burden was determined using Sound Transit's comparison of annual vehicle-miles for each alternative and the pollutant emission rate data from PSRC. The pollutant emission rates vary depending upon the year examined (2007, 2020, and 2030) and the average speed, ranging from 37.7 to 38.3 mph.

Tailpipe emissions for existing conditions were compared to the 2020 and 2030 No Build Alternatives to illustrate the future trend in pollutant emissions for the Puget Sound regional airshed. Table 4.6-3 summarizes tailpipe emissions for the existing, No Build 2020, and No Build 2030 conditions as well as for the low-ridership and high-ridership projects as determined through ridership modeling. Emission rates for all pollutants would fall from existing conditions to 2030 under all ridership conditions represented. All criteria pollutants under the build alternatives would be well below existing conditions and at or below the No Build pollutant levels. Other pollutants would also be at or below the No Build pollutant levels.

Mobile Source Air Toxics

Regional impacts of MSATs must be evaluated in accordance with the Federal Highway

Administration's (FHWA's) Interim Guidance on Air Toxic Analysis in National Environmental Policy Act (NEPA) Documents (FHWA, 2009). Currently, there are no established criteria for determining when MSAT emissions should be considered a problem. For the purpose of MSAT impact evaluation under NEPA, FHWA has developed a tiered approach for analyzing MSATs. Based on this tiered approach, the East Link Project would be considered to have a low potential MSAT effect because it would not add substantial traffic volumes or change the traffic mix considerably from the No Build Alternative. As a result, the East Link Project would generate minimal air quality impacts for CAA criteria pollutants and would not be linked with any special MSAT concerns. Consequently, MSATs impacts are not expected to occur as a result of the East Link Project. EPA has developed several emission control programs for vehicle engines and fuels that will reduce MSATs over the next 20 years. These programs include reformulated gasoline, a product of CAA legislation that targets the nation's more acute O_3 nonattainment areas; National Low Emissions Vehicle standards; Tier 2 motor vehicle emission standards and associated gasoline sulfur control requirements; heavy-duty engine standards and on-highway diesel sulfur control requirements; the final rule for non-road diesel engines; and proposals for marine and locomotive engines and the 2001 MSAT rule toxic emissions performance standard. According to an FHWA analysis, using the EPA's MOBILE6.2 model (2003), implementing these control programs will decrease MSAT emission rates by 72 percent from 1999 to 2050, even if VMT increases by 145 percent (FHWA,2009).

Regardless of the build alternative chosen, emissions would likely be lower than existing levels in the 2030 design year as a result of the EPA's national control programs. Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control measures; however, the magnitude of the EPA-projected reductions is remarkable in that MSAT emissions in the project vicinity are likely to be lower in the future in nearly all cases.

4.6.3.2 Localized Operational Impacts

The East Link Project would generate minimal air pollutant emissions during operation because the proposed trains are electrically powered. However, air quality in the project vicinity could be affected by changes in traffic flow and volumes locally and regionally and as a result of increased vehicular traffic near the light rail stations and park-and-ride lots.

Light rail is anticipated to improve air quality by shifting commuters from motor vehicle to train ridership. Compared to the No Build Alternative, increased use of light rail is projected to decrease peak-hour morning (AM) and afternoon (PM) traffic volumes locally and regionally, although intersections located near the stations and park-and-ride lots would experience an increase in traffic congestion as more commuters transfer at these locations.

corridor. WASIST uses predefined traffic data to estimate the project-generated CO emissions by inputting a combination of worst-case scenarios simultaneously into the model in an effort to produce the highest possible level of CO emissions. High-volume, signalized intersections with a level of service (LOS) of D or worse would produce traffic congestion that could cause localized CO hotspots, thereby impacting air quality.

Traffic data were collected for the project to determine which intersections would meet this criterion and further degrade the LOS from D to E or F under the future build alternatives. Screened intersections meeting this criterion underwent a CO hot-spot modeling analysis. If the worse-case intersections do not cause an air quality impact, all other intersections would have a lesser impact. Exhibits 4.6-2 through 4.6-4 show all the intersections considered and those that meet the WASIST criteria for modeling CO concentrations.

The initial step in the WASIST modeling process is to perform a "pre-screen." If the pre-screen does not provide a passing result, a complete WASIST analysis is required to better estimate the intersection's impact on ambient CO concentrations. Additional information on how the WASIST model was applied to this project is described in the technical memorandum in Appendix F4.6. The results of the WASIST model are also presented in Appendix F4.6.

Affected intersections were modeled using the WASIST pre-screening analysis. However, they all initially were above the WASIST pre-screen analysis, requiring a complete WASIST analysis, for existing conditions and for the future No Build and build alternatives. The tables in Appendix F4.6 provide the model results at all intersections requiring analysis. Although there are CO NAAQS for both 1-hour and 8-hour averaging periods, past monitoring data show that only the 8-hour NAAQS of 9 parts per million (ppm) has the potential to be exceeded, and, therefore, only the 8-hour CO concentrations from the highest receptor at each affected intersection are reported.

EXHIBIT 4.6-4
Segment D and E Intersections Analyzed for CO Concentrations with WASIST Model

The modeled CO concentrations did not exceed the NAAQS in each case and therefore passed the complete WASIST analysis. Modeled results indicated that the highest CO concentrations would occur under existing conditions. However, these CO levels are still below the 8-hour standard. When existing CO concentrations levels were compared to those in future years, for both the No Build Alternative and the build alternatives, the results indicated a decreasing trend with time.

Higher concentration levels under existing conditions can be attributed to an older vehicle fleet with higher emissions. Under the future years of 2020 and 2030, modeled CO levels decrease as vehicle emissions decrease based on expected future improvements in inspection and maintenance programs, improved vehicle fuel efficiency, and improvements directed by the SIP.

The differences in CO concentrations between the No Build and build alternatives rely mainly on their differences in traffic volume or longer vehicle idle times at intersections. Generally, build CO concentrations were similar to No Build concentrations, except in a few instances where increases in CO concentrations under the build alternatives could be attributed to an intersection’s proximity to one of the stations or park-and-ride lots. Minor CO concentration variations would occur among the build alternatives because of increases in traffic volumes resulting from an alternative and increases in extended idle times causing vehicles to remain longer at intersections. However, as shown in the tables presented in Appendix F4.6, none of the CO concentrations are predicted to exceed the 8-hour CO standard of 9.0 ppm with the project alternatives. The modeled impact levels for the various alternatives are between 3.6 ppm and 6.6 ppm at intersections. Often there are negligible differences between the No Build and the build alternatives at congested intersections, but none exceed the 8-hour standard. A summary by segment is provided in the following subsections.

Segment A

With *Preferred Interstate 90 Alternative (A1),* intersection operations generally would improve in Seattle, especially along Rainier Avenue, because East Link would reduce the amount of auto demand on this corridor and near the Interstate 90 (I-90) HOV ramp (D2 Roadway) terminus at 5th Avenue South and Airport Way/Dearborn Street (vehicle access to the ramp would be restricted). Although these improvements would not change the LOS conditions in the project study area, the reduction in volume would provide a slight air quality benefit at intersections in Seattle. This is indicated by the negligible decrease in CO concentrations from 4.2 to 4.1 during 2020 at the Rainier Avenue South and 23rd Avenue South intersection. CO concentrations for the other affected intersections of South Royal Brougham Way and 4th Avenue South, Dearborn Street, and Rainier Avenue South under this alternative would remain unchanged for both 2020 and 2030.

On Mercer Island, nearly all intersections would maintain a LOS of C or better for future No Build and build alternatives. However, the intersection of North Mercer Way and Island Crest Way would experience a degradation of LOS from existing to future 2020 and 2030 conditions. However, as shown in Appendix F4.6, CO concentrations would remain below the current 8-hour standard of 9 ppm. Further CO concentrations would remain unchanged between the No Build and build levels for 2020 and 2030. All predicted CO concentrations would not exceed current standards, so no potential air quality impacts would be likely.

Segment B

In general, with *Preferred 112th SE Modified Alternative (B2M) to C11A*, CO concentrations at the affected intersections would remain unchanged from the No Build Alternative for both 2020 and 2030. However, minor traffic increases would occur under this alternative that would affect the intersections at 112th Avenue SE/Bellevue Way SE and SE 8th Street/118th Avenue SE, resulting in a negligible increase in CO concentrations over the No Build Alternative in both 2020 and 2030. As shown in Appendix F4.6, CO concentrations for the No Build and build alternatives for 112th Avenue SE and Bellevue Way SE would be 4.6 ppm for 2020 and 5.2 ppm for 2030, which remains below the current 8-hour standard of 9 ppm.

Furthermore, CO concentrations for *Preferred Alternative B2M to C9T* would also experience a negligible increase in CO concentrations over the No Build Alternative similar to *B2M to C11A* at the intersection of 112th Avenue SE and Bellevue Way SE for 2020.

Depending on which Segment B alternative is chosen, minor traffic increases would occur and slightly degrade the LOS from the No Build Alternative at the following intersections:

- Bellevue Way SE at the park-and-ride lot intersection would be affected by an increase in traffic to the site under all other Segment B alternatives except BNSF Alternative (B7).

- 112th SE At-Grade Alternative (B2A) is expected to create additional vehicle delay at the Bellevue Way SE and 112th Avenue SE intersection.
- Alternative B7 is expected to degrade intersection operations at SE 8th Street and 118th Avenue SE due to the increase in vehicle traffic from the 118th Station.

These minor traffic increases would result in minor differences in CO concentrations among the alternatives.

All CO concentrations with the other alternatives in Segment B would experience the same CO concentrations as *Preferred Alternative B2M* for both build years 2020 and 2030. No air quality impacts would be expected from *Preferred Alternative B2M* or any of the other alternatives in Segment B.

Because all predicted CO concentrations would not exceed current standards, no potential air quality impacts would be likely.

Segment C

Modeled CO concentrations for *Preferred 108th NE At-Grade Alternative (C11A)* are nearly identical to the No Build Alternative. For 2020, negligible increases in concentrations with *Preferred Alternative C11A* could be found at the following intersections, resulting from minor increases in vehicle volumes from the No Build to *C11A*:

- Main Street and 112th Avenue NE
- NE 4th Street and 108th Avenue NE
- NE 4th Street and 110th Avenue NE
- NE 8th Street and 106th Avenue NE
- NE 8th Street and 116th Avenue NE

For 2030 there would be no increases in CO concentrations from the No Build Alternative to *Preferred Alternative C11A*. At the intersection of NE 4th Street and 110th Avenue, the CO concentrations would have a negligible decrease with *Preferred Alternative C11A*: 4.8 ppm with No Build Alternative and 4.6 ppm with *C11A*. In this instance, traffic volumes decrease slightly under *Preferred Alternative C11A*.

There would be slight increases in CO concentrations between the No Build Alternative and *Preferred Alternative C11A* in 2020 that would not occur in 2030 because improvements in signal timing and vehicular traffic patterns would reduce congestion and offset the increases in traffic in 2030. As a result, CO concentrations would remain unchanged between the No Build Alternative and *Preferred Alternative C11A* in 2030.

Because all predicted CO concentrations would not exceed current standards, no potential air quality impacts would be expected with *Preferred Alternative C11A*.

Modeled CO concentrations for *Preferred 110th NE Tunnel Alternative (C9T)* are similar to those of *Preferred Alternative C11A*. There would be some negligible changes in CO concentrations from the No Build to *Preferred Alternative C9T* for 2020 and 2030.

In general, there would be a shift to mass transit from personal vehicle use with the East Link Project. The use of transit is expected to provide a slight air quality benefit at intersections in the Downtown Bellevue area. Intersections that would be altered under the various Segment C alternatives due to turn movements, travel lane reduction, safety improvements, and the median requirements for the light rail tracks would not have a noticeable impact on CO concentrations. All CO concentrations for the other Segment C alternatives would be nearly identical to the No Build Alternative. None of the modeled CO concentration exceeded 5.4 ppm under the 2030 Segment C build alternatives.

Modeled CO concentrations for all other alternatives are relatively similar to the CO concentrations predicted for *Preferred Alternatives C11A* and *C9T*. Because all predicted CO concentrations would not exceed current standards, no potential air quality impacts would be likely with any Segment C build alternative.

Segment D

Preferred NE 16th At-Grade Alternative (D2A) would result in minor changes in traffic volumes at the NE 20th Street and 140th Avenue NE, NE 20th Street and 148th Avenue NE, and NE 40th Street and 156th Avenue NE intersections. The increases and decreases in traffic volumes would result from changes in vehicular circulation patterns that cause CO concentrations to fluctuate accordingly. For example, for the NE 20th Street/140th Avenue NE and NE 20th Street/148th Avenue NE intersections, CO concentrations would have a negligible decrease in 2020 from the No Build levels as traffic volumes slightly decrease at these intersections. CO concentrations increases would be negligible near the NE 40th Street and 156th Avenue NE intersection in 2020.

CO concentrations under *Preferred Alternative D2A* would remain unchanged from both the 2020 and 2030 No Build Alternative at the intersection of NE 24th Street and 148th Avenue. This intersection also has the highest modeled future CO concentration of 5.7 ppm.

However, this modeled CO concentration does not exceed the 8-hour concentration standard of 9 ppm. Furthermore, modeled CO concentrations for all other Segment D alternatives are identical to the predicted CO concentrations for *Preferred Alternative D2A*.

No potential air quality impacts would be expected because predicted CO concentrations for all Segment D alternatives would not exceed current standards. None of the modeled CO concentration exceeded 5.7 ppm under any of the Segment D 2030 build alternatives.

Segment E

Modeled CO concentrations for *Preferred Marymoor Alternative (E2)* are nearly identical to the No Build Alternative. However, in 2030 for the Redmond Way and SR 520 eastbound intersection, No Build concentrations are 6.1 ppm and *Preferred Alternative E2* concentrations are 6.6 ppm. The negligible increase in CO concentrations from No Build to *Preferred Alternative E2* can be attributed to the increase in wait times for vehicles at intersection signal lights. For the No Build Alternative, the green light times would be longer, thus allowing more vehicles to pass through the intersection and leaving fewer vehicles to sit idle. Idle vehicles generate more emissions than vehicles traveling at a steady and consistent speed.

Modeled CO concentrations for the other Segment E alternatives were nearly identical to the No Build Alternative, with the exception of the intersection of Redmond Way and SR 520 eastbound in 2030. An increase of 0.5 ppm from No Build to Segment E build alternatives can be explained with the addition of the SE Redmond Station. Adding this station would change the light's cycle length times at this intersection, resulting in an increase of vehicles delayed at red lights. However, a CO concentration of 6.6 ppm is below the federal 8-hour standard of 9 ppm.

The modeled CO concentrations for all other alternatives in Segment E are relatively similar to the CO concentrations predicted for *Preferred Alternative E2*. Because all predicted CO concentrations are below current standards, no potential air quality impacts would be likely result from *Preferred Alternative E2* or the other Segment E alternatives. None of the modeled CO concentration exceeded 6.6 ppm under the 2030 build alternatives.

Greenhouse Gases from Operation

GHG emissions are normally presented as the total CO_2 equivalent (CO_2e) released. The CO_2e emissions take into account the global warming potential of chemical emissions from a source. The combustion of fossil fuels emits small amounts of N_2O and CH_4. The global warming potential of N_2O and CH_4 are, respectively, 310 and 21 times that of CO_2. The total CO_2e emissions take into account the other pollutants and their global warming potential.

Currently, transit operations are expected to reduce the automobile use that causes a high percentage of GHG emissions. The East Link Project would result in lower VMT and would reduce GHG emissions. Additional savings in VMT can be attained from transit-oriented development that is expected to occur around light rail stations. This discussion is expanded in Chapter 5, Cumulative Impacts.

A quantitative analysis was conducted on GHG emissions from project operations in the design year 2030. The potential CO_2e impacts during project operation include reductions from the decreased vehicular traffic, measured as VMT, resulting from the East Link Project. Brief methodology, assumptions, and a summary of the calculations for the GHG emissions analysis from construction and operation are provided in Appendix F4.6.

The analysis estimated fuel or energy consumption by vehicle type from vehicles operating in the region and the project study subarea. The East Link Project study subarea for GHG is defined as the transportation area zones that make up roughly the North and East subareas of the Sound Transit District and includes more than 90 percent of the East Link riders in the 2030 projections. Because most of the potential riders are within the subarea, it can be assumed that the majority of the impacts would occur within this subarea.

Regional and subarea transit bus VMT was allocated between diesel, hybrid, compressed natural gas, and trolley buses. As shown in Table 4.6-3, transit bus VMT was allocated by vehicle type based on the number of vehicles operated by the four transit authorities for the region. The U.S. Department of Energy produces the energy usage for different modes in terms of British thermal unit (Btu) per vehicle mile. This source was also used for light rail energy use. For buses, automobiles, and trucks, EPA's MOBILE6—Mobile Source Emission Factor Program (2003)—was applied as provided by the PSRC.

TABLE 4.6-3
Regional and Subarea Bus Fleet Mix

Type	Region	Subarea
Diesel	69%	75%
Hybrid	12%	19%
Compressed natural gas	11%	0%
Trolley	8%	6%
Total	**100%**	**100%**

Notes:
Regional fleet mix based on number of transit vehicles operated by Sound Transit, King County Metro, Pierce Transit, and Community Transit.

Subarea fleet mix based on fleet VMT reported by King County Metro.

Three fuel types are presented in Table 4.6-4. For this analysis, all energy consumption from trolley, light rail, and commuter rail was converted to gallons of gasoline (g/gal). However, an additional step was applied to East Link energy use because the energy provided for light rail includes non-GHG emission energy sources. Electricity for East Link would be drawn from Seattle City Light for those portions of the route in Seattle and from Puget Sound Energy for the portions on Mercer Island, Bellevue, and Redmond. Both Seattle City Light and Puget Sound Energy rely heavily on hydropower and other non-petroleum energy resources that generate low GHG emissions (See Section 4.10, Energy). In fact, Seattle City Light plans to continue to meet a goal of zero net GHG emissions.

TABLE 4.6-4
CO_2e Emission Rates by Fuel Type

Fuel Type	CO_2e g/gal
Diesel	10,156
Gasoline	8,970
Compressed natural gas	7,899

g/gal = gallons of gasoline

Source: The Climate Registry, 2008.

In 2006 and 2007, Puget Sound Energy sources ranged between 30 to 40 percent zero-GHG-emission and may soon offer clients the ability to choose their energy sources, thereby offering Sound Transit the option to only use non-GHG-emitting power, such as wind, hydropower, and solar. Sound Transit plans to use higher than average hydropower. Therefore, to be conservative, energy use for East Link was reduced by an additional 30 percent and light rail miles in Seattle were removed from the GHG calculation.

Table 4.6-5 shows the total projected GHG emissions for the No Build Alternative and 2030 high- and low-ridership conditions with the build alternatives. The build scenarios show that there would be a range of 21,535 to 28,835 metric tons annual reduction of CO_2e emissions in the region due to the reduction of VMT and the use of cleaner energy sources for operating the light rail system. The gains would be more pronounced in the subarea, as this is where most of the change in VMT would occur. Under the No Build Alternative, the subarea would contribute almost one-third of the Puget Sound region GHG emissions. Implementing the East Link Project could reduce the region's yearly GHG by almost 0.2 percent. This would result in a savings of 0.4 percent annually for the subarea.

According to EPA's website (EPA, 2011), the regional saving for the high ridership East Link Project estimated as 28,835 metric tons of CO_2e per year is the equivalent of the following:

- Supplying electricity for 3,175 homes for 1 year
- Consuming 60,834 barrels of oil per year
- Planting 670,735 trees or saving 248 acres of forest from deforestation

In addition, according to the California Air Resource Board, improving automobile speeds up to 46 miles per hour would reduce GHG emissions (Urban Land Institute, 2008). Sound Transit traffic modeling shows that the build alternatives would result in improved traffic speeds over the No Build Alternative on I-90 during congestion periods. For example, the build alternatives would improve traffic flow by 2 to 4 mph on average in the PM peak-hour commute.

However, there are some places where traffic flow would decrease by 1 mph (westbound between Mercer Island and Seattle) and other places where speeds would improve by as much as 30 mph (eastbound from Mercer Island). Overall, the project would result in an additional reduction in GHG emissions from improved traffic flow during project operation (see Chapter 3 of this Final EIS).

TABLE 4.6-5
Greenhouse Gas Emissions in Terms of CO_{2e} During Light Rail Operation

	2030 No-Build	2030 High Ridership	2030 Low Ridership	Units
Regional				
Daily CO_2e	52,322	52,243	52,263	Metric tons CO_2e emissions daily
Daily CO_2e reduction	Not applicable	79	59	Metric tons CO_2e daily
Annual CO_2e reduction	Not applicable	28,835	21,535	Metric tons CO_{2e} annually
Subarea				
Daily CO_2e	18,807	18,736	18,755	Metric tons CO_2e emissions daily
Daily CO_2e reduction	Not applicable	71	52	Metric tons CO_2e daily
Annual CO_2e reduction	Not applicable	25,915	18,980	Metric tons CO_{2e} annually

Source: Entech Consulting Group GHG Emissions Calculations, 2010

Sound Transit adopted a Sustainability Initiative in 2007 that promotes and implements more energy-efficient alternatives than current practices. According to the initiative, Sound Transit will integrate efficient operating practices at existing and new facilities, use energy-saving equipment to reduce energy demand, and maximize intermodal transit connections to reduce automobile VMT. Many of these practices have been incorporated in the Central Link Initial Segment that opened in 2009. The implementation of the sustainability initiatives will reduce energy consumption and thus GHG emissions during East Link operations.

The East Link Project also includes the operation of a maintenance facility. The maintenance facility would be the equivalent of a light industrial site of approximately 18.344X10 Btu per year. Puget Sound Energy would provide power. Considering that over 30 percent of Puget Sound Energy is already provided by hydropower or other non-CO2e-emitting sources, the East Link maintenance facility would produce approximately 1,503 metric tons of CO_2e per year. This is approximately 8 percent of the yearly GHG emissions from the East Link Project.

4.6.3.3 Project Construction Impacts

During construction, the release of particulate emissions (airborne dust) associated with site preparation, fill operations, and roadway improvements is anticipated to be the primary cause of potential short-term air quality impacts from the East Link Project.

Emissions from construction equipment also are anticipated and would include CO, PM, NO_x, and VOCs. Site preparation and roadway construction would involve clearing, cut-and-fill activities, grading, removing or improving existing roadways, and paving roadway surfaces.

Construction-related impacts on air quality would be greatest during the site preparation phase because most engine emissions are associated with the excavation, handling, and transport of soils to and from the site. If not properly controlled, these construction-related activities would temporarily generate PM_{10}, $PM_{2.5}$, and small amounts of CO, SO_2, NO_x, and VOCs. Sources of fugitive dust would include disturbed soils at the construction site and trucks carrying uncovered loads of soils. Unless properly controlled, vehicles leaving the site would deposit mud on local streets, which could be an additional source of airborne dust after it dries. PM_{10} and $PM_{2.5}$ emissions would vary from day to day, depending on the nature and magnitude of construction activity and local weather conditions. PM_{10} and $PM_{2.5}$ emissions would depend on soil moisture, silt content of soil, wind speed, and the amount of equipment operation. Larger dust particles would settle near the source, while fine particles would be dispersed over greater distances from the construction site.

In addition to PM_{10} and $PM_{2.5}$ emissions, heavy trucks and construction equipment powered by gasoline and diesel engines would generate CO, SO_2, NO_x, and VOCs in exhaust emissions. If construction traffic were to reduce the speed of hauling trucks and other vehicles in the area, CO emissions from traffic would increase slightly while those vehicles are delayed. These emissions would be temporary and limited to the immediate area surrounding the construction site. SO_2 is generated by oxidation during combustion of organic sulfur compounds contained in diesel fuel. Some phases of construction, particularly asphalt paving, would result in short-term odors from VOC in the immediate area of paving sites. Such odors would be quickly dispersed below detectable thresholds as distance from the sites increases.

Increases in air pollutant emissions from construction of the East Link Project are considered temporary impacts. The duration of civil construction for any one particular location along the East Link corridor is expected to range from about 2 to 5 years. The most intense activity, such as site preparation, would occur during the initial phase of construction.

Little is known at this time about the number and exact types of equipment that would be required for each alternative. In lieu of analyzing project construction impacts for each alternative within the different segments, Sound Transit selected two components that would involve a diversity of equipment and materials and potentially high dust and emissions in a concentrated area. These were evaluated to present a worst-case scenario for any given project construction period. The components that were chosen are the proposed garage at the South Bellevue Park-and-Ride Lot and the SE Redmond Maintenance Facility (MF5).

A projected pollutant emission inventory was developed for the parking garage and maintenance facility using a spreadsheet tool titled Road Construction Emissions Model Version 5.2, which was developed by the Sacramento Air Quality Management District (2007). This emission spreadsheet uses a number of default assumptions and detailed, project-specific information. The available project data included specific information about the disturbed surface area, the quantity of cut-and-fill material, and the construction duration period. The model's defaults were used for the number and types of project construction equipment needed, the number of construction workers commuting to the job sites, and the length of their commute.

Because there are no state or local guidelines for evaluating the degree of impact from construction pollutant emissions, criteria proposed in the *California Environmental Quality Act (CEQA) Air Quality Handbook*, prepared by the South Coast Air Quality Management District (SCAQMD, 1993), were used as a guideline for this project. The CEQA Air Quality Handbook establishes recommended daily thresholds for construction-related emissions from construction projects. Construction-related emissions that exceed these established threshold levels are considered to be a concern.

Table 4.6-6 presents the model emission results for the South Bellevue Park-and-Ride garage and MF5. The projected emissions from both of these facilities are essentially the same because, given the estimates that were available at the time of this analysis, they occupy approximately the same area (12 to 15 acres).

TABLE 4.6-6
Projected Construction Emissions

Pollutant	South Bellevue Park-and-Ride Garage (pounds per day)	SE Redmond Maintenance Facility (MF5) (pounds per day)	SCAQMD Construction Emission Threshold (pounds per day)
CO	32	32	550
NO_x	31	31	100
Reactive organic gases	7	7	75
Exhaust PM_{10}	2	2	NA
Fugitive dust	5	5	NA
Total PM_{10}	7	7	150

Source: CH2MHILL Construction Emission Calculations, 2008

CO	carbon monoxide
NO_x	oxides of nitrogen
PM	particulate matter
SCAQMD	South Coast Air Quality Management District

The construction emissions for the two facilities would be substantially below the daily emissions thresholds set by SCAQMD.

Greenhouse Gases from Construction

GHG associated with the construction phase of the East Link Project are expected to be consistent with other projects of this scale. In large-scale construction projects, the major sources of GHG emissions are fossil-fueled construction equipment (mobile and stationary). It was conservatively assumed that all of the fossil fuel used during construction would be diesel. The CO_2e factor for diesel used in the analysis is from The Climate Registry General Reporting Protocol (The Climate Registry, 2008).

The amount of GHG emissions produced by fossil-fueled construction equipment is directly proportional to the quantity of fuel used. Construction fuel consumption is based on recent experience in building light rail in the Seattle region and provides an order-of-magnitude estimate of GHG emissions. The estimate includes the following factors:

- Transportation of construction materials, waste, and fill material
- Equipment used during construction site preparation
- Construction of the rail track and guideway, rail stations, associated park-and-ride lots, and a representative maintenance facility

The fuel used also encompasses the difference in building at-grade, elevated, retained-cut, and tunnel profiles; specific station design; parking structures; and the need for a maintenance facility for the project.

Table 4.6-7 shows the range of the GHG emissions for constructing the project. The construction of one maintenance facility is included in the full project emissions calculation, which alone would be approximately 1,740 metric tons of CO_2e.

TABLE 4.6-7
CO_2e Emission for Construction of Full-Length Project

Project	Tons of CO_2e
High construction emissions	173,197
Low construction emissions	94,893
Potential difference in CO_2e	78,304

Source: CH2MHILL Construction Emission Calculations, 2008
CO_2e carbon dioxide equivalent

The highest potential GHG emissions for the East Link Project would result from building *Preferred Alternative A1* and Alternatives B2E, C2T, D3, and E1. The lowest GHG emissions for the project would result from building *Preferred Alternative A1* and Alternatives B7, C7E, D5, and E4. The difference would be largest in Segment C, where alternatives vary among at-grade, elevated, and tunnel profiles. The tunnels would have almost five to six times more GHG emissions than the elevated profile, and almost four times the emissions for at-grade profile alternatives. In all other segments, alternatives with extensive elevated profiles would result in more GHG emissions to construct over at-grade profile alternatives, but generally only about 10 percent more. One additional difference occurs in Segment D, where Alternative D3 would include a portion of retained-cut profile. Construction of this alternative would have almost 60 percent higher GHG emission than that of the lowest CO2e emissions alternative (Alternative D5), which is extensively elevated but also has two fewer stations than all other Segment D alternatives.

4.6.3.4 Hot Spot Analysis at Station Platforms

The East Link Project is unique in that several of the proposed stations (specifically, the Rainier, the Mercer Island [both in *Preferred Alternative A1*], and the Hospital/Ashwood stations) are along heavily traveled highways that may expose passengers standing at station platforms to CO concentrations resulting from automobile tailpipe emissions. The project would not substantially change the volumes of vehicular traffic in the project vicinity; however, the station platforms are representative of sensitive locations where passengers would be exposed to CO concentrations. The project vicinity is in an attainment maintenance area for CO. As presented in Table 4.6-8, data collected from CO monitoring sites in the project vicinity demonstrate that the area has not exceeded the CO NAAQS in the last 5 years.

TABLE 4.6-8
Ambient Air Quality Monitoring Data from CO Monitoring Sites in the Project Vicinity

Pollutant	Maximum Concentration (ppm)		
	2006	2007	2008
Beacon Hill Monitoring Site			
1-hour average	2.3 ppm	1.4 ppm	1.4 ppm
8-hour average	1.5 ppm	1.0 ppm	0.9 ppm
Bellevue Monitoring Site			
1-hour average	5.1 ppm	3.9 ppm	3.4 ppm
8-hour average	3.7 ppm	2.7 ppm	2.3 ppm

Source: EPA, (2010).

CO	carbon monoxide
ppm	parts per millions

A hot spot modeling analysis was performed for the East Link Project to quantify passenger CO exposure levels at station platforms. The WASIST modeling tool is formatted to estimate CO concentrations only at signalized intersections. Due to the stationary platforms locations near non-signalized highways, the WASIST model cannot be used to estimate CO concentrations at these specific locations. Therefore, two additional modeling programs approved by EPA—MOBILE6.2 and CALINE3—were used to predict CO concentration levels.

The highest predicted 1-hour CO concentration levels were obtained and compared to the EPA NAAQS 1-hour CO primary standard of 35 ppm. The longest amount of time passengers are expected to wait on the station platform is assumed to be 15 minutes. There is currently no 15-minute CO standard; however, it is assumed that if the highest predicted 1-hour CO standard is below the NAAQS, then the passengers' exposure levels for 15 minutes would also be acceptable.

Emission factors for 2030 were estimated using MOBILE6.2, a modeling program developed by the EPA to estimate current and future emissions from highway motor vehicles. This model was used to calculate the CO emission factor for use in the CALINE3 model. The CALINE3 model is used to calculate the dispersion of vehicle emissions and expected concentrations at select points in the vicinity of roadways. The CO emission factor is based on local climate, vehicle speed, and fuel and vehicle registration data specific to the Puget Sound region. Model inputs were provided by the PSRC (Peak, 2008).

Each station has a unique configuration, and the CALINE3 model was run separately for the Rainier, Mercer Island, and Ashwood/Hospital Stations. As shown in Table 4.6-9, the highest predicted 1-hour CO concentrations for all three station platforms were found to be well below the CO NAAQS 1-hour standard of 35 ppm.

TABLE 4.6-9
1-hour CO concentrations at Station Platforms

Station Name	1-hour CO concentrations (ppm)

4.6.4 Conformity Determination

Under the Clean Air Act, a transportation project located in a nonattainment or maintenance area for a given pollutant is required to meet a conformity determination with the SIP. Conformity requirements are met when a project does not cause or contribute to an exceedance of the NAAQS. In air quality maintenance areas, regionally significant projects are evaluated for their conformity to Air Quality Maintenance Plans (AQMP). Projects that conform to the plan are not expected to cause exceedances of the standard. The East Link Project would be located in the Puget Sound region, which is a maintenance area for CO, with a portion of the project also located in the Duwamish PM_{10} maintenance area. In the Puget Sound region, PSRC determines regional conformity by including a project in the Metropolitan Transportation Plan (MTP) and the RTIP.

The proposed project is included in the region's MTP, *Vision 2040/Transportation 2040* (PSRC, 2009), and in the *2010-2013 Regional Transportation Improvement Program* (PSRC, 2010), both of which have been found to meet the CO and PM_{10} conformity tests as identified by federal and state conformity regulations. *Transportation 2040* was adopted in May 2010. The East Link Project is in the regional plan and RTIP, which meets regional conformity. Therefore, the East Link Project has met the requirement of being included in the regional plans, which have been found to conform to the SIP.

A project-level conformity determination was performed by conducting a CO hot spot analysis on affected intersections in the project vicinity. For project level conformity, the 2030 horizon year is consistent with the RTP that was adopted at the time the East Link analysis began in 2006 (PSRC, 2001). Based on modeling, intersections in the project vicinity currently do not exceed the CO NAAQS. Affected intersections under all build alternatives would not create any new exceedances of the CO NAAQS. Therefore, the project meets conformity requirements for CO.

A PM_{10} project-level hot spot analysis is not required for the East Link Project because it is not a project of air quality concern based on the FHWA PM_{10} guidance (2006). Projects of air quality concern are defined in 40 CFR 93.123(b)(1).

Operation of the East Link Project is expected to provide an air quality benefit to the surrounding area due to the shift of bus ridership to light rail ridership. The development of the Bus Integration Plan was created jointly by Sound Transit and King County Metro to coordinate reasonably foreseeable future changes in transit operations with changes specifically associated with East Link Project operations (e.g., reducing or removing overlapping light rail and bus service or changing routes to feed light rail). The Bus Integration Plan would convert existing bus lines to rail lines, thereby decreasing bus VMT, which in turn would decrease diesel particulate emissions generated from bus operations.

Furthermore, this project meets conformity requirements for PM_{10} by its inclusion in the MTP, the AQMP, and the RTIP, which have been found to meet the conformity test for PM_{10}.

4.6.5 Potential Mitigation Measures

There would be no operational impact requiring mitigation because the East Link Project would provide a net benefit over the No Build Alternative. In particular with the preferred alternatives, air quality modeling demonstrates that no air quality impacts would be expected from project operation. All predicted CO concentrations for the preferred alternatives are below the 8-hour federal NAAQS for CO concentrations; therefore, no mitigation measures would be necessary. However, consistent with Sound Transit's sustainability policies, further reductions in fuel and energy use would continue to reduce GHG emissions for project operations.

For construction activities, PSCAA regulates particulate emissions (in the form of fugitive dust). Any emission of fugitive dust requires the use of best practices to minimize impacts. The general policy of PSCAA and WSDOT is to prevent and reduce fugitive dust resulting from construction activities so as not to injure human health, plants and animals, or property, and so as not to unreasonably interfere with the enjoyment of life and property. To comply with PSCAA and WSDOT policy of preventing air quality degradation, the following mitigation measures may be used as necessary and in accordance with standard practice to control PM_{10}, $PM_{2.5}$, and emissions of CO and NO_x during construction of the project. Several of these measures would also reduce GHG emissions.

- Spray exposed soil with dust control agent as necessary to reduce emissions of PM_{10} and deposition of particulate matter.
- Cover all transported loads of soils and wet materials before transport, or provide adequate freeboard (i.e., space from the top of the material to the top of the truck) to reduce PM_{10} and deposition of particulate during transportation.
- Provide wheel washes to reduce dust and mud that would be carried off site by vehicles and to decrease particulate matter on area roadways.
- Remove the dust and mud that are deposited on paved, public roads to decrease particulate matter
- Route and schedule high volumes of construction traffic to reduce congestion during peak travel periods and reduce emissions of CO, NO_x, and CO_2e where practical.
- Require appropriate emission-control devices on all construction equipment powered by gasoline or diesel fuel to reduce CO and NO_X emissions in vehicular exhaust.
- Use well-maintained heavy equipment to reduce CO and NO_X emissions, which may also reduce GHG emissions.
- Cover, install mulch, or plant vegetation as soon as practical after grading to reduce windblown particulate in the area.

The following other readily available mitigation measures could potentially be used:

- Encourage contractors to employ emissions reduction technologies and practices for both on-road and off-road equipment/vehicles (e.g., retrofit equipment with diesel control technology and/or use of ultra-low sulfur diesel).
- Implement construction truck-idling restriction (e.g., no longer than 5 minutes).
- Locate construction equipment and truck staging zones away from sensitive receptors as practical and in consideration of other factors such as noise.

Emissions of CO, NO_X, and VOCs are best controlled through use of new construction equipment and proper maintenance of this equipment. Use of low-sulfur diesel fuel controls emissions of SO_2. SO_2 and NO_x emissions are considered precursor to $PM_{2.5}$ emissions; therefore, reductions in SO_2 and NO_x will also help reduce $PM_{2.5}$ emissions. All mitigation measures must comply with local regulations governing air quality, including those for controlling fugitive dust during construction.

4.7 Noise and Vibration

4.7.1 Introduction to Resources and Regulatory Requirements

4.7.1.1 Noise and Vibration Basics

Noise

Noise is defined as unwanted sound; it is measured in terms of sound pressure level and is usually expressed in decibels (dB). The human ear is less sensitive to higher and lower frequencies than it is to midrange frequencies. To provide a measurement meaningful to humans, a weighting system was developed that reduces the sound level of higher and lower frequency sounds, similar to what the human ear does. This filtering system is used in virtually all noise ordinances. Measurements taken with this "A-weighted" filter are referred to as "dBA" readings.

There are two primary noise measurement descriptors that are used to assess noise impacts from traffic and transit projects, the Leq and the Ldn, described below:

- **Leq:** The equivalent sound level (Leq) is the level of a constant sound for a specified period of time that has the same sound energy as an actual fluctuating noise over the same period of time. The peak-hour Leq is used for all traffic and light rail noise analyses at locations with daytime use, such as schools and libraries.
- **Ldn:** The day-night sound level (Ldn) is an Leq over a 24-hour period, with 10 dBA added to nighttime sound levels (between 10 p.m. and 7 a.m.) as a penalty to account for the greater sensitivity and lower background sound levels during this time.

  The Ldn is the primary noise-level descriptor for light rail noise at residential land uses. Exhibit 4.7-1 is a graph of typical Ldn noise levels and residential land use compatibility. More detail on noise and noise descriptors are provided in the Noise and Vibration Technical Report (Appendix H2).

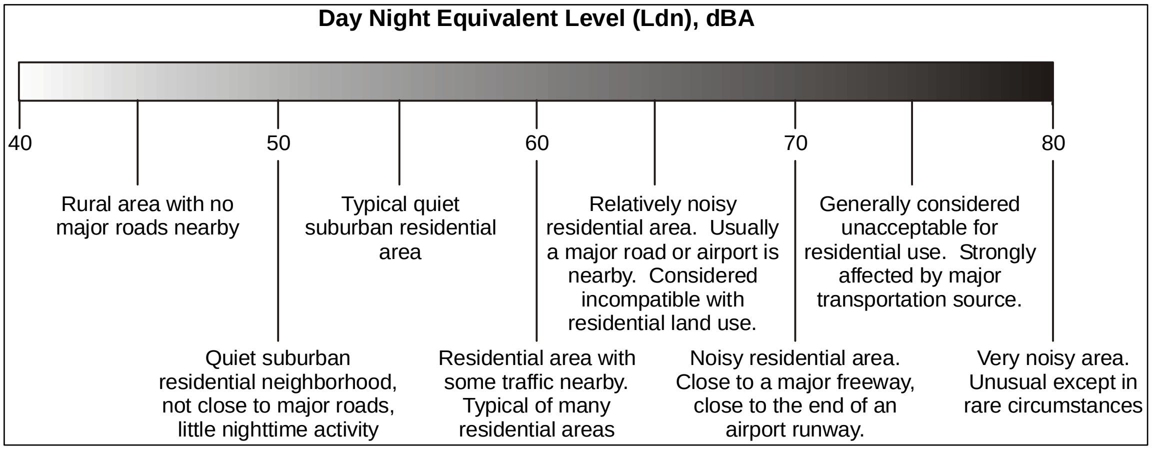
In addition to Leq and Ldn, there is also a descriptor called the Lmax. The Lmax is the loudest 1 second over a measurement period and is used in many local and state ordinances for noise coming from private land uses and for construction impact evaluation.

Vibration

Travel of light rail trains on trackways and guideways associated with the East Link Project would result in vibration that might be felt on adjacent properties. The project was analyzed for two types of vibration impacts:

- **Groundborne vibration:** the movement of the ground (vibration can be experienced either outdoors or indoors)
- **Groundborne noise**: noise generated by the movement of room surfaces, such as walls, resulting from vibration of a building (groundborne noise can only be experienced indoors)

Groundborne vibration can be described in terms of displacement, velocity, or acceleration when evaluating impacts from transit projects. Groundborne noise occurs as a perceptible rumble and is caused by the noise radiated from the vibration of room surfaces. Vibration above certain levels can damage buildings, disrupt sensitive operations, and cause annoyance to humans within buildings.



Day Night Equivalent Level (Ldn), dBA

The response of humans, buildings, and equipment to vibration is most accurately described using velocity or acceleration. Vibration velocity is used in this analysis as the primary measurement to evaluate the effects of vibration.

Exhibit 4.7-2 illustrates typical groundborne vibration velocity levels for common sources as well as thresholds for human and structural response to groundborne vibration. As shown, the range of interest is from approximately 50 vibration velocity decibels (VdB) to 100 VdB (i.e., from imperceptible background vibration to the threshold of damage). Although the threshold of human perception to vibration is approximately 65 VdB, annoyance does not usually occur unless the vibration exceeds 70 VdB.

4.7.1.2 Noise and Vibration Impact Criteria

The following sections provide an overview of the criteria used for evaluating East Link Project noise and vibration impacts, which are defined by the Federal Transit Administration (FTA) for transit-related noise and vibration and by the Federal Highway Administration (FHWA) for traffic-related noise. The FTA and FHWA analyses are performed based on actual land use, not land use zoning. Therefore, if a residence is located in an area that has been zoned commercial, the analysis still considers that location to be a residential land use.

Transit Noise Criteria

Noise impacts for the East Link Project are based on the criteria defined in the FTA guidance manual *Transit Noise and Vibration Impact Assessment* (2006). The FTA noise impact criteria are founded on well-documented research of community reaction to noise and are based on changes in noise levels using a sliding scale. Although more transit noise is allowed in neighborhoods with high levels of existing noise, as existing noise levels increase, smaller increases in total noise exposure are allowed than in areas with lower existing noise levels.

FTA's noise impact criteria are grouped into the following noise-sensitive land use categories:

- **Category 1**: Buildings or parks where quiet is an essential element of their purpose
- **Category 2**: Residences and buildings where people normally sleep, including residences, hospitals, and hotels where nighttime sensitivity is assumed to be important
- **Category 3**: Institutional land uses with primarily daytime and evening use, including schools, libraries, churches, and active parks

Ldn is used to characterize noise exposure for residential areas (Category 2). For other noise-sensitive land uses, such as outdoor amphitheaters and school buildings (Categories 1 and 3), the maximum 1-hour Leq during the facility's operating period is used. There are two levels of impact included in the FTA criteria; the interpretation of these two levels of impact is summarized below:

- **Severe impact:** Project-generated noise in the severe impact range can be expected to cause a substantial percentage of people to be highly annoyed by the new noise and represents the most compelling need for mitigation. Noise mitigation will normally be specified for severe impact areas unless there are extenuating circumstances that prevent it.

- **Moderate impact:** In this range of noise impact, the change in the cumulative noise level is noticeable to most people but might not be sufficient to cause strong, adverse reactions from the community. In this transitional area, other project-specific factors must be considered to determine the magnitude of the impact and the need for mitigation. These factors include the existing noise level, the predicted level of increase over existing noise levels, the types and numbers of noise-sensitive land uses affected, the noise sensitivity of the properties, the effectiveness of the mitigation measures, community views, and the cost of mitigating noise to more acceptable levels.

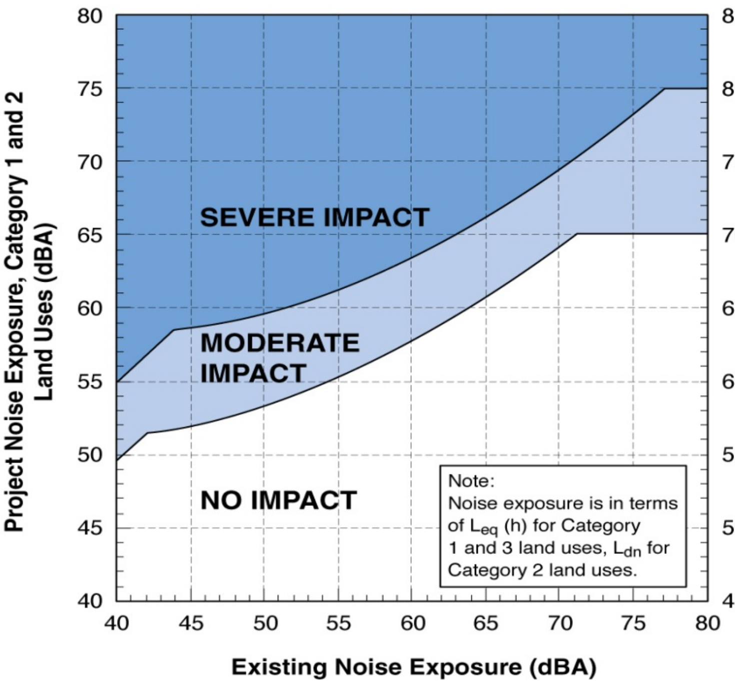

EXHIBIT 4.7-3
FTA Project Noise Impact Criteria
Source: Federal Transit Administration, 2006

Exhibit 4.7-3 depicts the noise impact criteria, as well as the existing noise exposure and the additional noise exposure from a transit project that would cause either moderate or severe impacts. The future noise exposure is determined by combining the existing noise exposure and the additional noise exposure caused by a transit project.

Parks are considered a special case under the FTA criteria. Whether a park is considered noise-sensitive is dependent on the typical use of the park. Parks that are primarily used for recreational activities or sporting events, such as football, baseball, soccer, and other active sports and recreation, are not considered noise-sensitive. Parks that are primarily used for passive activities, such as reading, conversation, and meditation, in contrast, could be considered noise-sensitive, but only those parks with low existing noise levels.

Parks along the proposed corridor were reviewed for use, existing noise levels, and proximity to major noise sources, such as highways and major arterial roadways. Each of these was considered when evaluating the parks and making the determination of the noise sensitivity of the park. In general, parks used for sporting activities or located near highways or major arterial roadways are not considered noise-sensitive.

Traffic Noise Criteria

The criteria for traffic noise impacts are taken from the FHWA Procedures for Abatement of Highway Traffic Noise and Construction Noise, Title 23, Code of Federal Regulation (CFR) Subchapter H, Section 772 (1982). Table 4.7-1 lists the traffic noise abatement criteria. A noise impact occurs if predicted noise levels approach the levels for specific land use categories listed in Table 4.7-1 or substantially exceed existing noise levels, as defined by the Washington State Department of Transportation (WSDOT). According to these regulations, only projects that include construction of new highway, reconstruction of existing highways with a substantial change in the horizontal alignment or vertical profile, or an increase in the number of through traffic lanes require a traffic noise analysis. If impacts are identified, then noise abatement must be considered. WSDOT is responsible for implementing FHWA regulations in Washington. Under WSDOT policy, a traffic-noise impact occurs if predicted noise levels are within 1 dB of the FHWA criteria shown in Table 4.7-1; therefore, a residential impact occurs at 66 dBA Leq, and a commercial impact occurs at 71 dBA Leq.

WSDOT considers a 10-dB increase in noise to be a substantial impact, regardless of the original noise level.

TABLE 4.7-1
FHWA Traffic Noise Abatement Criteria

Land Use Category		Hourly Leq
Type A	Lands on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose	57 dBA (exterior)
Type B	Picnic areas, recreation areas, playgrounds, active sports areas, parks, residences, motels, hotels, schools, churches, libraries, and hospitals	67 dBA (exterior)
Type C	Developed lands, properties or activities not included in the above categories	72 dBA (exterior)
Type D	Undeveloped land	—
Type E	Residences, motels, hotels, public meeting rooms, schools, churches, libraries, hospitals and auditoriums	52 dBA (interior)

Source: FHWA Procedures for Abatement of Highway Traffic Noise and Construction Noise (23 CFR 772)

WSDOT policy states that reducing the distance between a noise-sensitive property and traffic lanes by half (or increasing the noise level by 3 dBA) constitutes a substantial change in the horizontal alignment or vertical profile of a roadway, and therefore would also require a traffic noise analysis.

Transit Vibration Criteria

FTA's groundborne vibration impact criteria are based on existing land use and planned train frequencies. Table 4.7-2 shows the criteria for a general vibration assessment. The FTA vibration criteria are applied primarily to residential (including hotels and other places where people sleep) and institutional land uses. Commercial land uses are only considered when they contain vibration-sensitive uses, such as medical offices or sensitive manufacturing equipment. The criterion applied to these locations is dependent on the sensitivity of the use. Some buildings, such as concert halls, recording studios, and theaters, can be very sensitive to vibration but do not fit into any of the three categories listed in Table 4.7-2. Due to their sensitivity, these buildings usually warrant special attention during the vibration analysis.

Within the project corridor, these buildings include the theater at Meydenbauer Center, Bellevue Arts Museum, Overlake Hospital Magnetic Resonance Imaging (MRI) Unit, Overlake Hospital Optical Surgery Unit, Group Health Medical Center, and Children's Hospital Bellevue Clinic and Surgery Center (BCSC). Based on consultation with these facilities, the existing sensitive uses have been identified at the locations described below.

The following criteria apply for these locations:

- Theater at Meydenbauer Center and Bellevue Arts Museum: 72VdB for vibration, 35 dBA for groundborne noise.
- MRI Units at Overlake Hospital, Group Health Medical Center, and Children's Hospital BCSC: 60 VdB for vibration, no criterion for groundborne noise because vibration-sensitive equipment is not sensitive to groundborne noise.

TABLE 4.7-2
Groundborne Vibration and Noise Impact Criteria for Light Rail Transit Service Frequency

Land Use Category	Groundborne Vibration Impact Levels (VdB re 1 micro inch/second): Frequent Events	Groundborne Noise Impact Levels (dB re 20 micro Pascals): Frequent Events
Category 1: Buildings where low ambient vibration is essential for interior operations	65 VdB[a]	N/A[b]
Category 2: Residences and buildings where people normally sleep	72 VdB	35 dBA
Category 3: Institutional land uses with primarily daytime use	75 VdB	40 dBA

[a] This criterion limit is based on levels that are acceptable for most moderately sensitive equipment, such as optical microscopes. Vibration-sensitive manufacturing or research would require detailed evaluation to define the acceptable vibration levels. Verifying lower vibration levels in a building often requires special design of the heating, ventilation, and air conditioning (HVAC) systems and stiffened floors.

[b] Vibration-sensitive equipment is generally not sensitive to groundborne noise.
VdB vibration velocity decibels

- Overlake Hospital Optical Surgery Unit: 54 VdB for vibration, no criterion for groundborne noise because vibration-sensitive equipment is not sensitive to groundborne noise.

Table 4.7-2 includes separate FTA criteria for groundborne noise—the "rumble" that can radiate from the motion of room surfaces in buildings due to groundborne vibration. The vibration of floors and walls causes them to act like loudspeakers, generating noise due to the movement of the surfaces.

Although expressed in dBA, which emphasizes the more audible middle and high frequencies, the criteria are set lower than they are for airborne noise to account for the annoying low-frequency character of groundborne noise. Because airborne noise often masks groundborne noise for aboveground transit systems (i.e., at-grade or elevated), groundborne noise criteria are primarily applied to light rail operations in a tunnel where airborne noise is not a factor. For above-grade transit systems, groundborne noise criteria are applied only to buildings that have sensitive interior spaces that are well insulated from exterior noise.

Washington State Noise Criteria

The State of Washington has a noise control ordinance that applies (together with local noise regulations) to general construction activities, park-and-rides, and maintenance facilities. The Washington State Noise Control Ordinance (WAC 173-60) does not contain a section specific to highway or light rail noise. State law exempts mobile noise sources, including freight rail, aircraft in flight, and vehicles traveling in public right-of-way, as well as safety warning devices (i.e., bells). For stationary land uses with noises originating from outside public roadways and rights-of-way, the Washington State Noise Control Ordinance defines three classes of property usage and the maximum noise levels allowable for each (Table 4.7-3). For example, the noise caused by a commercial property must be less than 57 dBA at the closest residential property line. Between 10 p.m. and 7 a.m., the maximum allowable levels shown in Table 4.7-3 are reduced by a 10-dBA "penalty."

In addition to the property line noise standards, there are exemptions for short-term noise exceedance based on the minutes per hour that the noise limit is exceeded (Table 4.7-4). Local noise limits for construction equipment and specific exceedance exemptions are discussed in Section 4.7.3.5, Impacts during Construction.

TABLE 4.7-3
Washington State Noise Limits

Property Usage	Maximum Allowable Sound Level (dBA)		
	Residential	Commercial	Industrial
Residential	55	57	60
Commercial	57	60	65
Industrial	60	65	70

Local Noise Ordinances and Regulations

Because the East Link Project covers several cities, including Seattle, Mercer Island, Bellevue, and Redmond, several additional local noise ordinances are applicable to construction activities, park-and-rides, maintenance facilities, and other ancillary project-related facilities. Most of the cities in the corridor have adopted noise control ordinances similar to WAC 173-60. However, local noise ordinances can include different provisions from the State law. For example, Bellevue applies its exemption for construction noise more stringently, with fewer evening and weekend hours considered exempt. Mercer Island has a noise nuisance code, which would not be applicable to the project, and the WAC 173-60 would govern construction noise. The City of Seattle has a Noise Control Ordinance that is also similar to the WAC 173-60 for ancillary facilities; however, Seattle has an updated section that is specifically for construction that would be applicable to project construction in Segment A. Summaries of the applicable noise regulations for each city are provided in Appendix H2.

4.7.1.3 Methodology

The light rail noise and vibration analysis was performed in accordance with FTA's *Transit Noise and Vibration Guidance Manual* (revised May 2006). An FTA screening level analysis was performed during the initial alternative screening. The noise and vibration analysis that follows was performed using current conceptual project design files and follows the detailed analysis methods described in the FTA manual.

Light rail noise and vibration impacts were evaluated using measured noise and vibration levels from Sound Transit's fleet of light rail vehicles. Detailed noise and vibration prediction models were developed using the methods given in the FTA manual. Input to the models is described in Sections 4.7.3.1 and 4.7.3.2. Locations identified with noise or vibration impacts are considered for noise abatement or vibration reduction options.

A traffic noise analysis was also performed for those locations where project construction would require a substantial movement of the horizontal alignment or vertical profile of existing roadways. Traffic noise levels were projected using FHWA's Traffic Noise Model (TNM) and following the FHWA methods for predicting traffic noise levels. Traffic noise impacts were identified using the WSDOT traffic noise abatement criteria.

4.7.2 Affected Environment

This section summarizes land uses along the project corridor, as well as existing noise and vibration levels measured for the East Link analysis. Exhibits 4.7-4 and 4.7-5 show where existing noise and vibration were measured. More detailed maps showing the locations of the noise-monitoring sites and planned land uses are provided in Appendix H2.

4.7.2.1 Noise- and Vibration-Sensitive Land Uses

While a more detailed presentation of land use can be found in Section 4.3, Land Use, of this Final EIS, the following land uses are summarized for their potential sensitivity to noise and vibration. Most identified land uses are sensitive to both noise and vibration. The exceptions include outdoor parks, which may be noise-sensitive depending on usage, but are not vibration-sensitive, and vibration-sensitive equipment (such as MRI equipment in a hospital), which is not sensitive to noise. It is important to note that the noise and vibration analysis is based on existing land use and not zoning. For example, if a residence is legally located in an area that was rezoned for commercial use, the property would still be considered as a residence for the analysis.

For most of the project corridor, land use and zoning appear to match. Areas that are in transition include the southern end of Downtown Bellevue, the area near Lake Bellevue, and some areas along the former BNSF Railway corridor in Redmond. Other areas where land use is planned to change in the future based on current zoning include the Bel-Red corridor and the Overlake neighborhood. Long-term monitoring locations were measured for 24 hours, while short-term monitoring locations were measured for 20 minutes. Table 4.7-5 summarizes the noise levels at these monitoring locations as measured in February and March 2007, March 2009, September and October 2010, and February 2011. A discussion of land use and noise levels by segment is given below.

Segment A

Land use near the connection to the existing Downtown Seattle transit tunnel is mainly commercial; however, there are multifamily residences on the upper floors of Uwajimaya Village at 6th Avenue South and South Lane Street, where the route is in the transit tunnel. The route continues eastbound along the D2 Roadway, remaining in the existing Interstate 90 (I-90) corridor to the Mount Baker Ridge Tunnel. Land use along this section of Segment A is mainly commercial until it reaches 12th Avenue South, where there is a large group of single- and multifamily residences. The route then transitions from the tunnel to the floating bridge through an area that is primarily single-family residential.

Land use along Mercer Island is primarily single-family residential with multifamily apartment buildings near the Mercer Island Station. At the east side of Mercer Island, land use is primarily single-family residential with some office buildings south of the highway.

Judkins Park and Playfield is located near the entrance to the Mount Baker Ridge Tunnel. Other parks in Segment A include Taejon Park and East Portal Park. There are also several parks on Mercer Island, including Park on the Lid and Luther Burbank Park, both of which are near I-90. None of these parks are considered noise-sensitive under the FTA criteria because of their proximity to I-90 and the high existing noise levels.

Five locations were monitored in Segment A, one long term and four short term. Existing noise levels along Segment A are dominated by traffic noise from area highways, including Interstate 5 (I-5), I-90, and major arterial roadways. The measured existing Ldn near Segment A in the Seattle area was 69 dBA. Peak-hour noise levels measured at two different representative locations between 4 p.m. and 5 p.m. were 68 dBA Leq. This noise level is typical for sites near major highways and transportation corridors. Noise levels measured at three sites on Mercer Island ranged from 54 to 65 dBA Ldn.

[a] Sites shown on Exhibits 4.7-4 and 4.7-5

[b] This site was near the tennis courts, which is below grade and well shielded from traffic noise on 112th Avenue SE and SE 6th Street.

[c] This site was near the Bellevue Club Hotel, approximately 75 feet from 112th Avenue SE with some shielding.

Segment B

Land use along Segment B consists primarily of residences and parks, with some institutional and commercial uses. Land use in the southern end of Segment B, near Lake Washington, includes single-family residences and Enatai Beach Park. Land use along Bellevue Way is primarily residential from I-90 to Downtown Bellevue, although there are several churches and some commercial structures north of its intersection with 112th Avenue SE.

Major sources of noise in Segment B include traffic noise from I-90, I-405, Bellevue Way SE, and 112th Avenue SE. Mercer Slough Nature Park and Winters House, a historic structure used for nonresidential uses, are both located along the east side of Bellevue Way SE. The parts of the Enatai Beach Park and the Mercer Slough Nature Park that could be affected by the proposed project are near a major highway or major arterial roadways, including I-90 and Bellevue Way, and therefore are not considered noise-sensitive under FTA criteria. Land use along the west side of the 112th Avenue SE is entirely single- and multifamily residential, with commercial use on the east side transitioning to mixed commercial and hotel use from SE 8th Street to the boundary with Segment C.

Land use along the BNSF Alternative (B7) includes Mercer Slough Nature Park, multifamily residences, and commercial land use.

The only parklands in Segment B considered noise-sensitive under the FTA criteria are interior portions of Mercer Slough Nature Park; these parts of the park are 350 feet or more from the proposed alternatives. The portions of Mercer Slough Nature Park adjacent to the project are already dominated by traffic noise from Bellevue Way, I-90, and I-405.

Noise monitoring was conducted at 20 sites, 7 of which were long-term sites. Overall peak-hour noise levels in south Bellevue ranged from 50 to 72 dBA Leq. Maximum noise levels between I-90 and 112th Avenue SE ranged from 67 to 80 dBA Lmax, with an average of 74 dBA Lmax. North of the intersection of Bellevue Way SE and 112th Avenue SE, maximum noise levels on Bellevue Way or along 112th Avenue SE and vicinity ranged from 75 to over 96 dBA Lmax. The highest noise levels were measured at locations near I-90 and along Bellevue Way SE and 112th Avenue SE. Along the residential areas on Bellevue Way and 112th Avenue SE, noise levels are typical of those that would be expected to occur in a busy urban area near transportation corridors.

Segment C

Land use in the southern section of Segment C includes Surrey Downs Park and the Surrey Downs residential area, which transitions to commercial and office uses around Main Street. Surrey Downs Park is an active park with playfields, located along 112th Avenue SE, a major arterial roadway, and therefore is not considered noise-sensitive. Hotels and office parks are also present along the east side of 112th Avenue SE in this segment. Along Bellevue Way, north of the intersection with 112th Avenue SE under Bellevue Way Alternative (B1), land use is mainly single- and multifamily residential, and also includes the Bellevue Fire Department, churches, and some commercial uses. The commercial core of Downtown Bellevue is located on Bellevue Way between NE 4th Street and NE 8th Street, and includes several large shopping centers and office towers. There are some mixed-use buildings in Downtown Bellevue with commercial use on the ground floor and residential units on the upper floors. Other noise-sensitive properties in this area include the theater at Meydenbauer Convention Center and the Bellevue Regional Library. Parks along the downtown segment of the corridor include the Pocket Parks at NE 2nd Place and 110th Avenue NE, McCormick Park, and the Ashwood Playfield just west of the Bellevue Regional Library. The parks in this area do not have noise-sensitive uses and are near major arterial roadways and therefore are not considered noise-sensitive by the FTA. In addition, single-family residential land uses were identified along the northern edge of Downtown Bellevue, north of NE 12th Street. Sensitive land uses east of I-405 include Overlake Hospital, a broad range of nearby medical offices, and the Group Health medical building. There is also a multifamily residential area at the north end of Lake Bellevue, south of NE 12th Street.

Nineteen locations were monitored in Segment C: ten short-term and nine long-term. Peak-hour noise levels ranged from 55 dBA Leq in quiet areas away from major arterial roads to 75 dBA Leq near the Bellevue Hilton Hotel between 112th Avenue SE and I-405. Noise levels at residences along Bellevue Way ranged from 66 dBA Ldn for properties near the roadway to 60 dBA Ldn for properties shielded from roadway noise.

Along 112th Avenue, north of Surrey Downs Park, noise levels are dominated by local traffic and vehicles on I-405. Measured noise levels in this area ranged from 57 (at MC-5) to 75 (at MC-3) dBA Leq depending on the proximity to the roadway and shielding from existing structures. Noise levels at single-family residences along NE 12th Street ranged from 60 dBA Ldn for shielded properties (MC-13) increasing to as high as 70 dBA Ldn (MC-15) for residences directly adjacent to major arterial roads. The measured noise level at the Bellevue Regional Library (MC-10) was 62 dBA Leq. Noise levels for residences located near NE 12th Street ranged from 60 dBA Ldn at MC-13 to 70 dBA Ldn at MC-15. Finally, noise levels near Lake Bellevue (MC-19) were measured at 58 dBA Ldn. Maximum noise levels in Segment C ranged from 68 to 90 dBA Lmax, with maximum noise levels along 112th Avenue SE consistently in the mid to upper 80s decibel range. For example, over a 70-hour measurement period the Lmax at the condominiums on 112th Avenue SE (MC-15), ranged from 70 to 93 dBA Lmax, with an average Lmax of 80 dBA Lmax.

Segment D

Land use in Segment D is mainly commercial and light industrial, including retail, distribution facilities, and office spaces, which are generally not noise-sensitive. The only noise-sensitive land uses are the Children's Hospital BCSC on 116th Avenue NE, the Pacific Northwest School on NE 16th Street, and several single- and multifamily residences along 116th Avenue NE and on the south side of SR 520. The Overlake area is predominantly office parks and commercial land uses. Major sources of noise in this segment include traffic noise from SR 520 and major arterials, such as Bel-Red Road.

Six locations were monitored in Segment D: one long-term site and five short-term sites. The long-term site was at a residential area along 116th Avenue NE, near the 116th Maintenance Facility Alternative (MF1). The Ldn at residences along 116th Avenue NE was measured at 58 dBA. A short-term site was located near Highland Park, where the Leq and estimated Ldn were 65 dBA. Three short-term sites were located near the Overlake area, including one near the former Group Health Campus, one at the Overlake Assisted Living Center, and one near Microsoft. Estimated Ldn at these sites ranged from 65 to 71 dBA, with measured peak hour Leq levels ranging from 64 to 70 dBA Leq. Finally, a short-term monitoring session was performed at the Pacific Northwest School on NE 16th Street to assist with analysis of potential impacts at the school. The measured daytime noise level at the school was 56 dBA Leq, while the maximum noise level of 83 dBA Lmax was caused by truck traffic.

Segment E

Segment E begins in the commercial area at NE 40th Street and is adjacent to SR 520 and office parks until NE 51st Street. North of NE 51st Street, land use changes to single-family residential. Most residences in this area are located behind a sound wall along SR 520. Land use remains single-family residential to the West Lake Sammamish Parkway exit, where land use changes to multifamily residential, park, and commercial south of Downtown Redmond. Other land uses include Marymoor Park, and several other parks and green spaces, including Luke McRedmond Landing Park; Dudley Carter Park; the Edge Skate Park; and the Sammamish River, East Lake Sammamish and Bear Creek trails. All of these parks are near SR 520 and other major arterial roadways and are not considered noise-sensitive under FTA criteria due to active park uses and high existing noise levels. The one exception to this review is the portion of Marymoor Park that is near Lake Sammamish, which is 2,500 to 3,000 feet from the above-mentioned transportation noise sources, and is a portion of the park where low noise levels are part of its intended purpose. This portion of the park would be considered noise-sensitive under FTA criteria. Land use in the Downtown Redmond area varies but is mainly commercial and retail, with some mixed-use buildings that have residential use on upper floors. Major sources of noise in this segment include traffic noise from SR 520 and major arterials, such as West Lake Sammamish Parkway and SR 202.

There were five noise-monitoring locations in Segment E—two long-term sites and three short-term sites. The initial portion of all light rail alternatives in Segment E is along the east side of SR 520, shielded from nearby residences by existing sound walls. For locations with existing sound walls (represented by ME-1), Ldn ranged from 60 to 64 dBA, with peak-hour levels of 58 to 60 dBA Leq. A small group of homes along 156th Avenue NE does not have a sound wall (ME-2), and the measured Ldn was 68 dBA at this location. Noise at the multifamily units along 156th Place NE (ME-4) was also dominated by traffic on SR 520 and arterial roads, with an estimated Ldn of 64 dBA. The apartments along NE Leary Way and West Lake Sammamish Parkway (ME-5) had an estimated Ldn of 64 dBA, with most noise coming from the two main arterial roadways.

4.7.2.2 Vibration Measurements

Vibration measurement test sites were selected based on a review of aerial photographs, supplemented by a visual land use survey. Unlike noise, human response to vibration is not dependent on existing vibration levels. Humans respond to a new source of vibration based on the frequency of the events. Therefore, rather than measuring existing vibration levels, vibration measurements focused on characterizing the vibration propagation through the ground at representative locations in the project vicinity. This information was used as input for the analysis model. Eight sites, designated as Sites V-1 through V-8, were selected to represent a range of soil conditions near residences and other sensitive land uses along the rail corridor (Exhibits 4.7-4 and 4.7-5). Measurements were conducted at sites in Seattle, Bellevue, and Redmond in March 2007. A refined vibration analysis added six more sites, designated as Sites V-9 through V-14, which were selected to measure both soil conditions and building response at specific locations. Measurements were conducted in Bellevue during May 2010. Appendix H2 provides more detail.

4.7.3 Environmental Impacts

This section summarizes the models used to predict future noise and vibration levels and identifies where levels are predicted to exceed accepted criteria, causing an impact. These sources include light rail operation, changes in traffic due to the project, and construction activities. The projection models for these sources are described below. More detailed information is provided in Appendix H2.

Sound Transit has begun service on the Central Link light rail system in Seattle, which allows for operational noise monitoring that was not available at the time the 2008 Draft EIS was published. Noise measurements of actual train operations on Central Link allow more accurate noise modeling for future light rail conditions. This information, together with further design development, results in a more detailed noise impact analysis. New information includes updated reference noise levels from the existing fleet of light rail vehicles; locations of track crossovers; light rail operational characteristics for at-grade crossings, including train-mounted warning bells and gated crossing bells; and the effectiveness of lubrication to control wheel squeal.

4.7.3.1 Project Assumptions for Noise Analysis

Noise from East Link operations was modeled using the methods described in FTA's *Transit Noise and Vibration Assessment Manual* (2006). Input to the model included the following assumptions:

- Light rail train headways and speeds as described in Appendix E, Operating Plan Summary. The speeds depend on location, track type, and curvature, with a maximum operating speed of 55 miles per hour (mph). Measured reference noise levels for Sound Transit's new state-of-the-art, light rail vehicles equipped with wheel skirts. The reference measurements were taken along the ballast and tie segment of the Central Link Initial Segment in south Seattle in March 2010. The projected Ldn and Lmax assuming a train speed of 50 mph are shown in Appendix H2. Typical noise levels from a light rail pass-by range from 78 to 79 dBA at 50 feet at 40 mph. In comparison, a typical diesel bus produces 82 to 84 dBA Lmax at 50 feet at 40 mph.

- Elevations of sensitive properties and any shielding or other topographical features that could affect noise transmission.
- Plan, profile, and track type of all proposed East Link alternatives and design options. Track types that could be used under the different alternatives include at-grade with ballast and tie or embedded track, and direct fixation track types used for retained cut, retained fill, and elevated track sections. Special track work includes the locations of crossovers, where noise levels could increase as train wheel impact occurs when the train travels over a gap in the rail. For this analysis, measured increases in the light rail pass-by at crossovers was taken from the embedded crossovers along Martin Luther King Jr. Way South in Seattle.
- Noise levels associated with at-grade crossings, including the train-mounted and warning bells that would be used at crossings where gates would be required. The train-mounted bells were measured and validated in October 2009, with several supplemental measurements taken over the last 2 years. Under Sound Transit policy, train-mounted bells would be sounded as a train enters and exits a station and one to three times as it approaches and passes through an at-grade crossing. Train-mounted bells would produce maximum noise levels of 80 dBA Lmax at 50 feet between 6:00 a.m. and 10:00 p.m., reducing to 72 dBA Lmax between 10:00 p.m. and 6:00 a.m. For gated at-grade crossings, the warning bells mounted on the gates would sound as gates are lowered and raised; these bell volumes are adjustable but are typically set to 75 to 85 dBA Lmax at 10 feet near residential properties. For this analysis, the bell volume was conservatively assumed at 85 dBA and the bells were assumed to sound for approximately 25 seconds per train (10 to 13 seconds while rising and 10 to 13 seconds while lowering). Note that the train would also sound the bell as it travels to and through the crossing. As shown on Exhibit 4.7-6, noise levels from the warning bells would reduce at approximately 6 dB per doubling of distance. For example, a noise level of 80 dBA at 50 feet would reduce to 74 dBA at 100 feet.
- Wheel squeal was assumed on all curves with a radius of less than 600 feet, based on experience with the Central Link system. Wheel squeal is not included in the model because Sound Transit has committed to lubricating all curves in noise-sensitive areas with a radius of less than 600 feet, and preparing all curves with radius of less than 1,000 feet for lubrication.

The procedure used to evaluate the impacts of the project alternatives is based upon the change in the noise level that would be caused by each alternative and the number of dwelling units potentially affected by project noise. For this analysis, attenuation for the noise-reducing effects of ground coverage was not included, and all front-line receivers were assumed to have a line-of-sight view of the light rail trackway unless the trackway was in a retained cut, directly shielding the receptor from the tracks. This conservative methodology ensures that all potential noise impacts will be identified. This method is consistent with the FTA *Transit Noise and Vibration Manual*. The FTA noise assessment methodology was also applied to the park-and-rides and maintenance facilities, which are analyzed as stationary transit facilities.

All ancillary facilities would be analyzed using any applicable local noise ordinance or regulations. Therefore, all transit maintenance facilities and park-and-rides must meet the local noise ordinances. This means that the three maintenance base alternatives south of SR 520 in Bellevue and the proposed park-and-ride options would be required to meet the City of Bellevue noise ordinance. In addition, the maintenance base and park-and-rides in Redmond would be required to meet the City of Redmond noise control ordinance.

Traffic noise was evaluated where required by FTA and FHWA. Traffic noise was analyzed using the FHWA methods provided in the *Traffic Noise Abatement Policy and Procedures* (WSDOT, 2006). In accordance with FHWA policy, traffic noise was evaluated for specific locations, meeting the criteria described in Section 4.7.1.2.

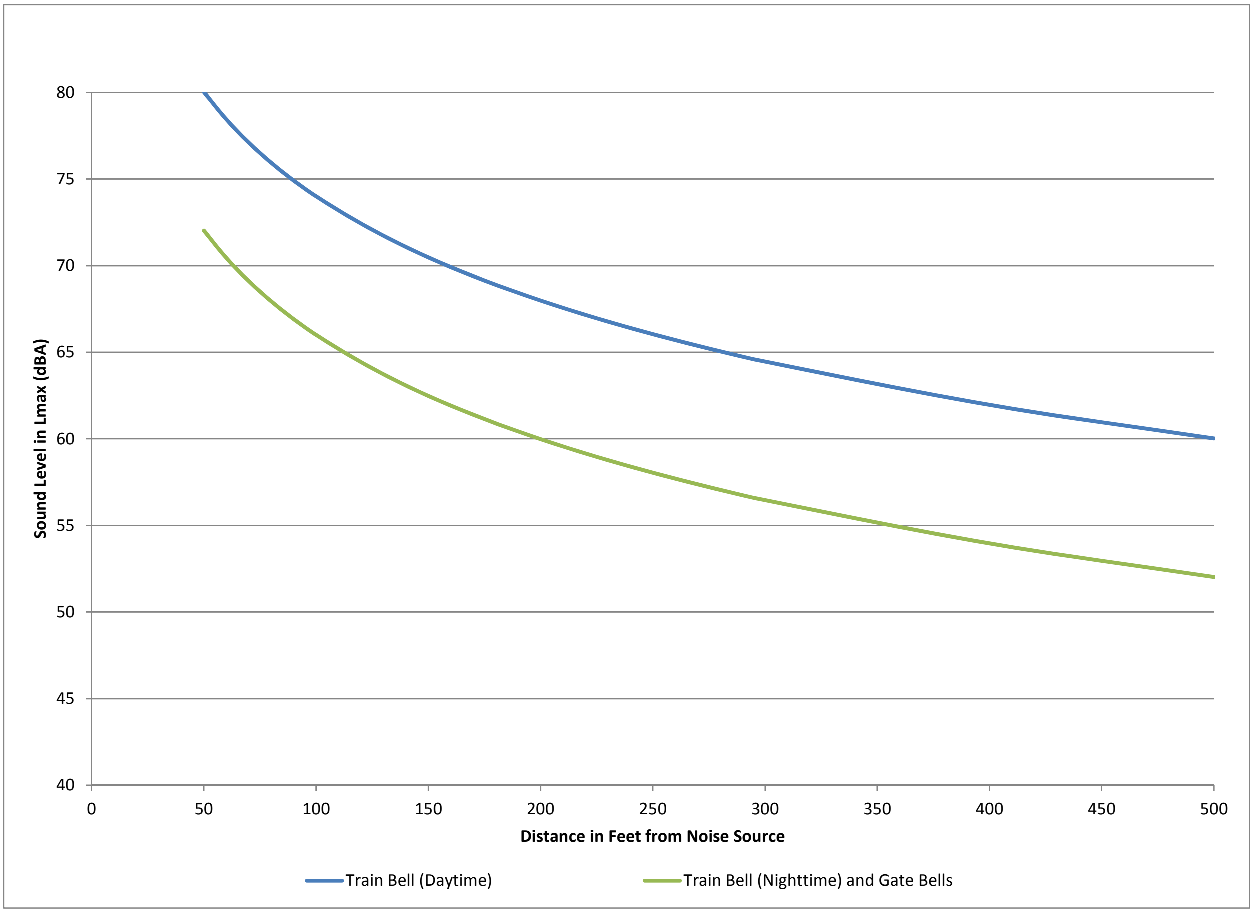

EXHIBIT 4.7-6
Noise Level Reduction with Distance (train bells and warning gate bells)

4.7.3.2 Project Assumptions for Vibration Analysis

Projections of groundborne vibration from East Link operations were based on the following assumptions:

- Vibration source levels were based on measurement data for the Sound Transit new light rail vehicles, as measured by Wilson Ihrig & Associates, Inc. (2007).
- Vibration propagation tests were conducted at representative sites along the corridor near sensitive receptors, as described in Section 4.7.2.2. The results of these tests were combined with the vehicle vibration source-level measurement data to provide projections of vibration levels from vehicles operating on the East Link Project alternatives.
- Light rail train headways and speeds are as described in Appendix E, Operating Plan Summary. The speeds are dependent on location, with a maximum operating speed of 55 mph.
- Wheel impacts at turnouts and crossovers typically cause localized vibration increases of 10 VdB.

The approach used for assessing vibration impact uses many of the same inputs as the noise impact assessment, such as speed, frequency of vehicle events, and distance from the receiver to the tracks. The vibration impact assessment combines vehicle characteristics with soil propagation properties to estimate vibration levels at sensitive receptors, as described in detail in previous sections. The FTA impact threshold for residential vibration is 72 VdB and the impact threshold for residential groundborne noise is 35 dBA, as presented in Table 4.7-2.

4.7.3.3 No Build Alternative

Under the No Build Alternative, there would be no project-related noise or vibration impacts. However, there are areas in the project vicinity where existing and future traffic noise levels would exceed the WSDOT criteria for traffic noise.

4.7.3.4 Impacts during Operations

Light Rail and Traffic Noise Impacts

The following sections present project-related light rail and traffic noise impacts before mitigation. Table 4.7-6 summarizes the noise impacts for the different alternatives, and the general locations of these impacts are shown in Exhibits 4.7-7 through 4.7-11. All noise impacts identified are discussed in this section by segment. Additional information about these impacts is provided in Appendix H2.

Potential impacts on wildlife would be construction-related only and are discussed in Section 4.8, Ecosystems Resources. The parks along the proposed alternatives were reviewed for sensitivity to noise, proximity to the alternative, and the potential for noise impacts. The only parks that are considered noise-sensitive under the FTA regulations are the sections of Mercer Slough Nature Park and Marymoor Park where peace and quiet are an essential part of the park's purpose. In both of these parks, these areas are several hundred feet from the project alternatives, highways, and major arterial roadways. The distance to these areas, and the existing shielding from structures and/or dense vegetation, are sufficient to reduce project noise to below the existing levels. All other park areas along the alternatives do not have noise-sensitive uses and are near major highway or arterial roadways, including I-90, SR 520, Bellevue Way SE, 112th Ave SE, NE 12th Street, and other major roadways, and therefore are not considered noise-sensitive under FTA criteria.

All proposed park-and-rides are at existing park-and-ride lot locations or in well-established transportation corridors that are not near noise-sensitive properties. The one exception to this is the proposed park-and-ride lot at the South Bellevue Station. While this park-and-ride lot would be located at the existing South Bellevue Park-and-Ride Lot, there are noise-sensitive properties nearby (i.e., homes to the west across Bellevue Way SE). In the sections that follow, park-and-ride lots are discussed briefly with the *Preferred Alternatives*. A more general discussion of the park-and-rides is provided at the end of each segment discussion.

Segment A

In Segment A, *Preferred Interstate 90 Alternative (A1)* is in the center of I-90 for most areas where there are noise-sensitive properties; therefore, no wayside noise impacts from light rail operations were identified. However, installing light rail on the I-90 floating bridge would require movable rail joints at the existing bridge expansion joints located at each end of the floating bridge structure, which could create added noise. There are no existing joints like the one currently proposed in a location that could be measured for noise levels. Based on the current evaluations, noise levels at a single home could meet the FTA criteria, with a predicted level of 63 dBA Ldn, when a worst-case noise impact from the movable rail joint is included in the analysis. If this impact occurred, it could be mitigated with sound walls near the joints. Sound Transit is currently constructing a prototype of the movable rail joint for testing purposes and will include measuring actual noise levels from the joint. Additional noise analysis will be performed to determine if this impact would actually occur and what mitigation measures would be best suited to reduce noise levels from the joints.

In addition to the expansion joints, there are four other standard crossovers in Segment A: one west of the Mount Baker Ridge Tunnel in Seattle, two on the floating bridge structure (between the two expansion joints), and another on Mercer Island near the Shorewood Drive overpass. The crossover near the tunnel is shielded from nearby residences and park areas by traffic safety barriers and was not predicted to increase noise levels in that area. The western crossover on the floating bridge structure is over 350 feet from any residence, while the eastern crossover is shielded from residences by the structure and traffic safety barriers.

The crossover on Mercer Island is located in an area that is well shielded from residences in a depressed segment of the highway, and therefore no noise impacts were predicted.

There are no new park-and-ride lots or maintenance bases in Segment A, and the new stations are along I-90. Therefore, there would be no noise-related impacts from ancillary facilities in Segment A.

Although there are several parks in Segment A, the parks are not considered noise-sensitive under the FTA criteria, or the parks are well shielded from the alternative and therefore would not be impacted by light rail operations. No other noise impacts from East Link operations or traffic are expected on any adjacent sensitive land uses in Segment A.

[a] Moderate and severe noise impacts using the FTA noise impact criteria

[b] Traffic noise impacts based on the FHWA 66 dBA Leq impact criteria.

[c] Under Alternative B1 all but nine of the traffic noise impacts would also have light rail noise impacts; conversely, there are only five light rail impacts that would not have traffic noise impacts. The total number of residences impacted (single- and multifamily) under this alternative would be 141; 5 would be impacted by light rail noise only, 9 would be impacted by traffic noise only, and 127 would be impacted by both traffic noise and light rail noise.

[d] Under Alternative B2A all but one of the traffic noise impacts would also have light rail noise impacts. The total number of residences impacted (single- and multifamily) under this alternative would be 79; 62 would be impacted by light rail noise only, 1 would be impacted by traffic noise only, and 16 would be impacted by both traffic noise and light rail noise.

[e] Under Alternatives B3 and B3 – 114th Extension Design Option all but one of the traffic noise impacts would also have light rail noise impacts. For B3, the total number of residences impacted (single- and multifamily) would be 84; 67 would be impacted by light rail noise only, 1 would be impacted by traffic noise only, and 16 would be impacted by both traffic noise and light rail noise. For B3 – 114th Extension Design Option, the total number of residences impacted (single- and multifamily) would be 78; 61 would be impacted by light rail noise only, 1 would be impacted by traffic noise only, and 16 would be impacted by both traffic noise and light rail noise.

[f] Under Alternative C1T all the traffic noise impacts are separate from light rail noise impacts. The total number of residences impacted (single- and multifamily) under this alternative would be 118; 100 would be impacted by light rail noise only, 18 would be impacted by traffic noise only, and 0 would be impacted by both traffic noise and light rail noise.

[g] Impacts for D2A - 120th Station and NE 24th Design Options would not vary from those of *Preferred Alternative D2A*.

Exhibit 4.7-11

Noise and Vibration Impacts, Segments D and E Other Alternatives

East Link Project

Segment B

Under *Preferred 112th SE Modified Alternative (B2M)*, the level of noise impacts would vary with the different connections to Segment C. Under *Preferred Alternative B2M* connecting to *Preferred Alternative C11A,* 79 moderate light rail noise impacts are predicted. Forty-one impacts would occur along the elevated segment from I-90 to the intersection with 112th Avenue SE, affecting single-family residences adjacent to SE 34th Street and Bellevue Way SE. North of the Bellevue Way SE/112th Avenue SE intersection, seven noise impacts are predicted at the single-family residences west of 112th Avenue SE, near SE 17th and SE 14th Streets. All noise impacts between I-90 and the retained cut at the Winters House would be related to the elevated guideway, a crossover near SE 30th Street, and, to a lesser extent, train bells at the station.

Under *Preferred Alternative B2M* connecting to *C11A,* 19 moderate noise impacts were also identified at the Bellefield Residential Park Condominiums, and 12 moderate impacts would occur at single-family residences along 111th Avenue SE just south of Surrey Downs Park.

Impacts in this area would be due to lower impact criteria as a result of lower ambient noise levels, gated crossings, and train wayside noise.

Under *Preferred Alternative B2M* connecting to *Preferred Alternative C9T*, 66 moderate light rail noise impacts were identified. Noise impacts from I-90 to 112th Avenue SE would be the same as with *Preferred Alternative B2M* connecting to *C11A*, with 41 moderate impacts along this portion of the alternative. There would also be six impacts on single-family residences west of 112th Avenue SE, near SE 17th and SE 14th Streets, and nine moderate noise impacts at the Bellefield Residential Park Condominiums. There would also be 10 moderate impacts at single-family residences along 111th Avenue SE just south of Surrey Downs Park.

Noise impacts with *Preferred Alternative B2M* connecting to *C9T* would occur for the same reasons as with *Preferred Alternative B2M* connecting to *C11A*, although some impacts would occur in different locations and with different severity. There are no roadway modifications that would move traffic closer to any noise-sensitive properties; therefore, no traffic noise impacts were identified under either of the *Preferred Alternative B2M* connection options.

Under *Preferred Alternative B2M* connecting to *C9T* with the East Main Station Design Option, the SE 8th Station would be relocated to the north in Segment C, and the crossover from Segment C would be relocated to Segment B, just north of SE 8th Street. This change would increase the noise levels at several homes along 111th Place SE by 1 to 4 dB over the *Preferred Alternative* station location. In addition, two of the moderate noise impacts would now be considered severe under the FTA criteria. The overall results under *Preferred Alternative B2M* connecting to *C9T* with the East Main Station Design Option are 64 moderate impacts, and two severe impacts.

The only park-and-ride under *Preferred Alternative B2M* is the South Bellevue Park-and-Ride, which is the same regardless of the connection to Segment C, and would be part of all Segment B alternatives except Alternative B7. The South Bellevue Park-and-Ride Lot is an existing facility, and under the proposed project would be improved to hold approximately 1,400 vehicles. Noise levels for park-and-ride operations were predicted using worst-case operational assumptions that all 1,400 parking spots would be used, and that approximately 450 buses per day would serve the facility in addition to light rail. The nearest residential properties to the park-and-ride are located west of the facility at 100 to 200 feet from the entrance and bus access areas. The projected Ldn at 100 feet from the park–and-ride is 60 dBA Ldn. Based on the existing Ldn noise levels of 67 to 69 dBA, the FTA criteria of 63 to 64 dBA Ldn is not predicted to be exceeded, and no noise impacts were identified. During final design, final station layout and bus route and light rail operations will be reviewed to ensure compliance with the City of Bellevue noise control ordinance.

Under the Bellevue Way Alternative (B1), there would be 4 severe light rail noise impacts, 128 moderate noise impacts, and 136 traffic noise impacts. Severe light rail noise impacts would occur near SE 30th Street because of the nearby crossover track. Traffic noise impacts along Bellevue Way SE, beginning near SE 30th Street, would result from roadway widening and occur at single- and multifamily structures along the project corridor. The total number of residences impacted (single- and multifamily) under Alternative B1 would be 141, and most would be impacted by both light rail noise and traffic noise.

With the 112th SE At-Grade (B2A) and 112th SE Bypass (B3) Alternatives, there would be 78 and 83 light rail noise impacts, respectively, and 17 traffic noise impacts each. The light rail noise impacts would occur along the elevated section from I-90, past the South Bellevue Park-and-Ride, and continue to the at-grade segment just south of the Bellevue Way SE/112th Avenue SE intersection. Light rail noise impacts were identified along 112th Avenue SE at the single- and multifamily residences from SE 17th Street to Surrey Downs Park.

Under Alternative B3 with the Alternative B3 - 114th Extension Design Option, the alternative would divert from 112th Avenue SE and transition to an elevated structure closer to I-405. This would result in a reduction in noise impacts when compared to Alternative B3. The B3 - 114th Extension Design Option would add a new gated crossing near the Bellefield Residential Park Condominiums resulting in three new noise impacts in this area. The design option would divert the alignment away from the single family residences along 111th Place SE, reducing the number of impacts in this area. This results in a net reduction of six noise impacts when compared with Alternative B3. Furthermore, the number of severe impacts is reduced from four to one with the B3 - 114th Extension Design Option.

Noise impacts under Alternatives B2A, B3, and B3 - 114th Extension Design Option would be caused by wayside noise from the elevated structure, crossovers, and, to a lesser extent, train bells at stations. Traffic noise impacts are projected to occur only between the South Bellevue Station and 112th Avenue SE as a result of road widening.

Under 112th SE Elevated Alternative (B2E), 85 moderate and 21 severe noise impacts are projected. There would be no traffic noise impacts under Alternative B2E. Because there are no at-grade crossings with this alternative, the only bell-related noise would be at the stations. Wayside noise from the elevated structure would be the dominant noise source for Alternative B2E.

Alternative B7 along the former BNSF Railway corridor would result in 176 light rail noise impacts, including 68 severe impacts resulting from a crossover near the Emerald Apartments. All other impacts to multifamily residences in this portion of the alternative would be due to higher speeds and close proximity to the alignment.

Under Alternative B7, a new park-and-ride would be constructed at the 118th Avenue Station. The station would be located along 118th Avenue near I-405, and no noise impacts were identified because of the high existing noise levels and lack of adjacent noise-sensitive receivers. The only other park in Segment B is the Enatai Beach Park, which is well-shielded from light rail noise by I-90, and therefore would have no project-related noise impacts All Segment B alternatives except Alternative B7 travel along the west side of Mercer Slough Nature Park. This park is bordered on two sides by two interstate highways—I-90 and I-405—and on a third side by the major arterial Bellevue Way SE, a park-and-ride, and a commercial office park, where "quiet" is not an essential element as outlined in the FTA criteria for park noise analysis. The active uses along the west perimeter include the boat launch, blueberry farm, and Winters House and are not considered noise-sensitive. The central portions of Mercer Slough Nature Park contain uses that do meet the criteria as noise-sensitive, such as nature watching and protected trails.

Sound Transit conducted a noise impact analysis for park users in noise-sensitive areas of the Mercer Slough Nature Park and also predicted noise levels for the areas of the park near Bellevue Way SE. Typical noise levels at the edge of the park, near Bellevue Way SE, are between 61 dBA and 67 dBA Leq. Noise levels in noise sensitive areas of the park, near the center, were measured at 58 dBA Leq during normal daytime hours. The FTA Category 3, which includes certain parks and recreational areas, was used to determine compliance with FTA noise impact criteria at the interior noise-sensitive parts of the park. Light rail noise levels from operation of *Preferred Alternatives B2M* to *C11A* or *B2M* to *C9T* are predicted to be lower than the existing noise levels in the interior noise-sensitive areas of the park, and are under the FTA noise impact criteria for a Category 3 land use.

Segment C

Under *Preferred 108th NE At-Grade Alternative (C11A)* connecting from *Preferred Alternative B2M,* 119 moderate and 65 severe light rail noise impacts are predicted. The 65 severe impacts would include several homes along 111th Avenue SE because of a nearby crossover and loss of shielding from displaced buildings. There would also be severe impacts at several multifamily units along 108th Avenue NE that would occur because of bells and proximity to the tracks. The other severe noise impacts would occur at the Lake Bellevue Village Condominiums and would be due to lower impact criteria because this areas has lower ambient noise levels. Severe impacts are also projected at the Coast Bellevue Hotel because of a nearby crossover and the proximity of the tracks to the hotel rooms. No roadway modifications would be required nor would there be any traffic noise impacts. *Preferred Alternative C11A* from Alternative B3, B7, or B3 – 114th Extension Design Option would result in 152 moderate and 52 severe light rail noise impacts. The change in the number and severity of impacts under Alternatives B3, B7, or B3 – 114th Extension Design Option would be due to the different alternative connections.

Preferred 110th NE Tunnel Alternative (C9T) connecting from *Preferred Alternative B2M* would result in 119 light rail noise impacts, including 62 moderate and 57 severe impacts. The severe impacts would occur at single-family residences along 111th Avenue SE, a multifamily building on NE 6th Street in Downtown Bellevue, and the Lake Bellevue Village Condominiums, and, depending on the location, would result from their proximity to the track, bells at crossings, and crossovers. *Preferred Alternative C9T* from Alternatives B3, B7, or B3 – 114th Extension Design Option would result in 88 moderate and 52 severe light rail noise impacts, with no noise impacts at the single-family residences along 111th Avenue SE because of the different Segment B connector alignments.

Under the C9T – East Main Station Design Option connecting from *Preferred Alternative B2M*, the relocation of the crossover and the new station site would reduce the number of severe impacts when compared to the scenario with the SE 8th Street Station. Relocating the crossover is the reason for the reduction in the severity of impacts. There would still be 119 noise impacts, however, with the East Main Station, 52 severe and 67 moderate.

The number and severity of noise impacts with other alternatives in Segment C would vary depending on the alternative and its connector from Segment B. South of Main Street, the Bellevue Way Tunnel Alternative (C1T) would be the only Segment C alternative with traffic noise impacts, the result of roadway modifications on Bellevue Way that would impact 18 multifamily units. Because the alternative profile transitions to a tunnel on Bellevue Way, there are no at-grade crossing bells in Segment C along Bellevue Way with Alternative C1T. Under Alternative C1T, 48 multifamily units along NE 6th Street would experience moderate impacts and 52 would experience severe impacts, including 36 hotel rooms at the Coast Bellevue Hotel and 12 units with severe impacts at the Lake Bellevue Village Condominiums. Impacts would result from proximity to tracks, a crossover near the Coast Bellevue Hotel, and low existing noise levels at the Lake Bellevue Village Condominiums.

106th NE Tunnel Alternative (C2T) connecting to Alternative B2A would likely have similar light rail impacts as predicted under Alternative C1T, but without any traffic noise impacts because both alternatives are similar when not in the tunnel through Downtown Bellevue. When connecting from Alternative B2E, Alternative C2T would result in 113 moderate and 66 severe light rail impacts. These impacts would result from the elevated profile and a crossover along 112th Avenue SE.

Alternative C2T connecting from Alternatives B3 or B7 would have 48 moderate light rail noise impacts and 16 severe light rail noise impacts at multifamily residences. There would also be 54 severe impacts and 18 moderate impacts at hotel rooms, for a total of 136 impacts under this alternative. Furthermore, Alternative C2T would not have any traffic noise impacts with any of its connection options. Impacts east of the tunnel would be due to proximity to the tracks, and a crossover.

The 108th NE Tunnel Alternative (C3T) would result in 26 noise impacts connecting from Alternative B2A, 105 impacts with an Alternative B2E connection, and 62 impacts connecting from Alternative B3 or B7. The Alternative B2A connection would have the fewest impacts because of the longer tunnel, with 21 multifamily impacts and 5 single-family impacts all located along NE 12th Street near 112th Avenue NE. With the Alternative B2E connection, there would be 15 single family impacts, 2 considered severe; 58 multifamily impacts, of which 12 are considered severe; and 32 hotel room moderate impacts. Finally, the Alternative B3 or B7 connection is predicted to have 18 severe impacts at the Bellevue Hilton Hotel along the side of the structure facing I-405.

Impacts under Alternative C3T near the northern tunnel portal would be the same for all connections because of wayside noise from the transition and elevated structure. South of Downtown Bellevue, the reason for and the location of impacts would vary with each different connection. With the Alternative B2A connection, there would be no impacts due to the tunnel. With the Alternative B2E connection, impacts along 112th Avenue SE would result from the elevated structure and crossover, while with the Alternative B3 or B7 connections, impacts would result from the proximity to the Hilton Hotel.

The Couplet Alternative (C4A) from the 112th SE At-Grade Alternative (B2A) connector would have the most noise impacts because of the high-rise apartments along 108th and 110th Avenues NE, with 435 moderate and 15 severe impacts throughout the alternative corridor. When connecting to Alternative B2E, Alternative C4A would have the same number of noise impacts as the connection to B2A. When connecting to Alternatives B3 or B7, Alternative C4A would have moderate light rail noise impacts on 420 residences and hotel rooms and additional severe impacts on 1 single-family residence and 18 hotel rooms.

South of Main Street, Alternative C4A impacts would result from general wayside noise and a crossover (with the Alternatives B2A or B2E connection), or proximity to a hotel (with the Alternatives B3 or B7 connection). North of Main Street, the impacts would be the result of train bells at each intersection from Main Street to (and including) NE 12th Street and noise from bells at gated crossings.

Under the 112th NE Elevated Alternative (C7E), the connection from Alternative B2A would result in 270 moderate and 12 severe light rail noise impacts. With the elevated connection from Alternative B2E, the number of impacts would be the same as with Alternative B2A. When connecting to Alternative B3 or B7, Alternative C7E would have 208 moderate light rail noise impacts and no severe impacts. All impacts would be related to wayside noise from the elevated structure and a crossover. There are no train bells or crossing bells under Alternative C7E, except at the NE 12th Street Station.

The 110th NE Elevated Alternative (C8E) would have moderate light rail noise impacts at 120 hotel rooms, 9 single-family residences, and 224 multifamily residences. This alternative would also have 72 severe light rail noise impacts at multifamily residences. Alternative C8E only connects to Alternatives B3 or B7. As with the other elevated alternatives, there are no at-grade crossings, so the only train bells would be at the stations; therefore, all impacts under Alternative C8E would be due to wayside noise from the elevated light rail.

The 110th NE At-Grade Alternative (C9A) connects to Alternatives B2A, B3, B3 – 114th Extension Design Option, or B7. Connecting from Alternative B2A, 241 light rail noise impacts are predicted, including 10 moderate and 4 severe impacts at single-family residences, 143 moderate and 16 severe impacts at multifamily residences, and 32 moderate and 36 severe hotel room impacts. With a connection to Alternative B3, B3 – 114th Extension Design Option or B7, that number would decline to 199 total impacts, with severe impacts at 2 single-family units, 16 multifamily units, and 36 hotel rooms. An additional 145 moderate impacts would also occur at residences and hotel rooms along this corridor.

Impacts under Alternative C9A would result from the crossover and elevated light rail south of Main Street, bells and proximity through the Bellevue central business district, and proximity and the crossover east of I-405.

The 114th NE Elevated Alternative (C14E), which is elevated along 114th Avenue NE, is predicted to have 16 severe impacts at multifamily residences, along with 96 severe and 36 moderate impacts at hotel rooms. Impacts would be the result of wayside noise from the elevated structure, crossovers and, at the Lake Bellevue Village Condominiums, low existing noise levels.

There are no park-and-rides in Segment C.

There are several parks and parklands in Segment C, including the Surrey Downs Park, Downtown Park, Ashwood Park, and McCormick Park. Surrey Downs Park is located along 112th Avenue SE, an established transportation corridor. The Downtown Park, as its name implies, is located in Downtown Bellevue, near NE 2nd Street. Ashwood Park and McCormick Park are both located near NE 12th Street, also an established transportation corridor. These parks were all reviewed for sensitivity to noise. Since all these parks have active uses and are located along established transportation corridors, none meet the FTA criteria for a noise-sensitive use.

Segment D

No light rail noise impacts were identified for *Preferred NE 16th At-Grade Alternative (D2A)*.

There are three potential park-and–ride lot locations with *Preferred Alternative D2A*: a new park-and-ride south of the corridor, just east of 120th Avenue SE or near the 130th Station; and expansion of the existing park-and-ride at the Overlake Transit Center Station near SR 520 and NE 40th Street. The new park-and-ride lots near the 120th and 130th Stations are both in existing industrial and commercial areas where no noise-sensitive receivers were identified; therefore, no noise impacts are projected. The expanded park-and-ride lot at Overlake Transit Center has no noise-sensitive receivers that would be impacted by facility operation.

With connections from the former BNSF Railway corridor (*Preferred Alternatives C11A* and *C9T*, and Alternatives C1T, C2T, C9A and C14E*)*, no noise impacts were identified for Alternative D2A - 120th Station Design Option, Alternative D2A - NE 24th Design Option, or NE 20th Alternative (D3). The NE 16th Elevated Alternative (D2E) is predicted to result in a noise impact at the Pacific Northwest Ballet School at the NE 16th Street/136th Place NE intersection. (The ballet school impact would only occur under Alternative D2E.) Alternative D5 would have severe noise impacts at 10 units at an apartment building near SR 520, off Northup Way. The noise impacts would be the result of proximity and the speed of the train in this area.

With connections from NE 12th Street (Alternatives C3T, C4A, C7E, and C8E), one moderate noise impact is predicted under Alternatives D2E, D3, and D5 at the new Children's Hospital facility on 116th Avenue NE; one moderate noise impact is predicted under Alternative D2E at the Pacific Northwest Ballet School; and 10 severe noise impacts are predicted under Alternative D5 at the same apartment identified in the previous paragraph for the connection from the former BNSF Railway corridor. No other noise impacts are expected under Alternative D3. The impact at the Children's Hospital BCSC would be due to the land use type and proximity to tracks.

Under Alternatives D2E and D3, the park-and-ride lot at the 130th Station would have no noise impacts, similar to *Preferred Alternative D2A*. Alternatives D2E, D3, and D5 would have a park-and-ride at the Overlake Transit Center Station at the existing Overlake Transit Center near SR 520 and NE 40th Street. The Overlake Transit Center is an existing facility, and no noise-sensitive receivers are predicted to have impacts related to the new park-and-ride operations.

There are no noise-sensitive parks located near any of the project alternatives in Segment D.

Segment E

Under *Preferred Marymoor Alternative (E2),* 148 severe and 33 moderate noise impacts were identified, for a total of 181 impacts. These include nine moderate and four severe impacts at single-family residences near SR 520 at West Lake Sammamish Parkway NE, 144 severe impacts at newly constructed multifamily units, and 24 moderate impacts at a hotel. No traffic noise impacts are predicted.

Noise impacts near SR 520 would be due to the higher speed of the train on the elevated structure. Noise impacts in other areas would result from crossovers, at-grade and gated crossings, and proximity of the light rail to sensitive land uses.

The park-and-ride under *Preferred Alternative E2* is located near an established commercial and industrial area east of Marymoor Park. No noise impacts are predicted at this site because of the existing land use, high existing noise levels from SR 520, and the commercial and industrial uses near the site.

Noise impacts under the Alternative E2 - Redmond Transit Center Design Option would be similar to the *Preferred Alternative E2*; however, this design option would have 81 moderate and 100 severe noise impacts, also totaling 181 noise impacts. The reason for this difference is because under this design option, one of the newly constructed multifamily buildings would not be impacted as it would be under *Preferred Alternative E2.* However, another building near the terminus would have the same number of severe impacts.

Under Redmond Way Alternative (E1), light rail noise impacts were identified at 9 single-family units, 236 multifamily units, and 72 hotel rooms. These include severe impacts at two single-family residences and 148 multifamily units.

The Leary Way Alternative (E4) would have 66 moderate noise impacts and 32 severe noise impacts related to light rail operations. No traffic or other noise impacts were identified in Segment E.

All new Segment E park-and-rides are located near an established commercial and industrial area, and no noise impacts were identified.

Parks and trails in Segment E include Marymoor Park, Luke McRedmond Landing Park, Dudley Carter Park, the Edge Skate Park, and the Sammamish River, East Lake Sammamish, and Bear Creek trails. Marymoor Park could be divided into three distinct sections: the section along SR 520, the central section, and the portion near Lake Sammamish. The section near SR 520 and the central section of Marymoor Park are primarily used for active sports; concerts; major events, such as circuses; and other events with large crowds, and/or amplified music or entertainment. These sections of the park are also located near SR 520 and adjacent to a commercial and industrial area to the east. Therefore, the sections of Marymoor Park along SR 520 and the central section would not be considered noise-sensitive under FTA criteria. Only the southern section of the Marymoor Park, near Lake Sammamish, was determined to meet the FTA criteria for a noise-sensitive area in a park. Because project alternatives are approximately 2,500 to 3,000 feet, or greater, from this section of the park, project noise levels are predicted to be below ambient levels and below FTA impact criteria, and no noise impacts are projected. The Luke McRedmond Landing Park, Dudley Carter Park, Edge Skate Park, and the Sammamish River, East Lake Sammamish, and Bear Creek trails parks are located along established transportation corridors, and therefore none meets the FTA criteria for a noise-sensitive use.

Maintenance Facilities

There are three maintenance facility alternative sites in Segment D, 116th Maintenance Facility (MF1), BNSF Maintenance Facility (MF2), and SR 520 Maintenance Facility (MF3). MF1 is located along 116th Avenue NE, just west of the former BNSF Railway corridor. MF2 is located just east of MF1, in an established industrial area. MF3 is located along the south side of SR 520, also in an established industrial area. MF1 is the only potential maintenance facility located near residential properties, as there are several single-family residences west of 116th Avenue NE. However, most of the buildings directly along 116th Avenue NE have been converted to office buildings. The new Seattle Children's Hospital BCSC is also located to the south of the MF1 site. Because a maintenance facility is considered a stationary transit facility that is near noise-sensitive properties, a noise analysis was performed using the following assumptions, consistent with FTA methods and criteria:

- Measured noise levels from the existing Sound Transit maintenance facility in South Seattle were used as baseline data.
- Train speeds would be limited to 5 mph inside the facility and horns would be sounded for at-grade employee crossings for safety.
- Wheel squeal noise on the tight-radius curves would not be as severe as noise from normal revenue train operations because of the slower speed and because some form of lubrication or friction modifier would be used to minimize or avoid noise from wheel squeal.
- The majority of noise-producing maintenance operations would occur inside the facility building, thus shielding nearby properties from the operations.
- The typical maximum number of trains at the facility is based on the proposed size and would not exceed 40 to 50 light rail vehicles.

Using the above assumptions, worst-case operational noise levels were projected at several single family residences along 116th Avenue NE and the Children's Hospital BCSC. The projected 24-hour Ldn ranged from 48 to 57 dBA at the sensitive receivers near MF1. A moderate noise impact was identified under the FTA criteria at the rear of the Children's Hospital BCSC. The impact would be due to the lower existing Ldn at the rear of the building, which results from the shielding the building provides from traffic noise along NE 12th Street. The noise analysis also included two single family residences that are located immediately west of MF1 across 116th Avenue NE, and four single family residences located slightly further west, and no noise impacts were identified at these six residences. It is important to note that most of the structures along 116th Avenue NE have been converted to commercial use.

Noise analysis was not conducted for the other two Segment D maintenance facility alternatives (MF2 and MF3) because there are no noise- sensitive properties nearby. Therefore, no noise impacts related to the operation of the maintenance facility alternatives MF2 or MF3 are anticipated.

If one of these maintenance facility alternatives were selected, then a full site design with the location of noise-producing sources would be completed, and a detailed noise analysis would be performed to ensure compliance with the City of Bellevue noise control ordinance. It is assumed that, because this is a fixed site, with most noise-producing activities occurring indoors, any potential noise related issues would be remedied through design modifications or treatments.

There is one maintenance facility alternative in Segment E, the SE Redmond Maintenance Facility (MF5), with two potential site locations. Both of the MF5 sites are located near the end of SR 520, in an established industrial area, with no nearby noise-sensitive properties. Due to the location of Alternative MF5, no noise analysis was conducted and no impacts are anticipated; however, when the site design is finalized, a detailed noise analysis would be performed to ensure compliance with the City of Redmond noise control ordinance.

Wheel Squeal

Wheel squeal is caused by the oscillation of the wheel against the rail on curved sections of train track. Curves with a radius of less than 600 feet will likely produce wheel squeal; curves with a radius of 600 to 1,000 feet have also been known to produce squeal, depending on train speed and track type. Light rail wheel squeal could produce maximum noise levels of 83 to 85 dBA at 50 feet. Table 4.7-7 lists all curves that would have a 600-foot radius or less, are not located in a tunnel, and have the potential for wheel squeal in proximity to noise-sensitive receivers.

Vibration and Groundborne Noise Impacts

Table 4.7-8 summarizes the vibration and groundborne noise impacts for the different build alternatives; the general locations of these impacts are shown in Exhibits 4.7-7 through 4.7-11. Groundborne noise is only assessed for tunnel sections or for buildings with sensitive interior spaces that are well-insulated from exterior noise. At other locations, because of the masking effects of airborne noise, groundborne noise is not a factor.

TABLE 4.7-7
Summary of Curves with Potential Wheel Squeal

Alternative	Curves with Radius of 600 Feet or Less
Segment A	
Preferred Interstate 90 Alternative (A1)	6th Avenue South; Dearborn Street and I-90 just east of 12th Avenue South
Segment B	
Preferred 112th SE Modified Alternative (B2M)	I-90 to Bellevue Way
Bellevue Way Alternative (B1)	I-90 to Bellevue Way
112th SE At-Grade Alternative (B2A)	I-90 to Bellevue Way
112th SE Elevated Alternative (B2E)	I-90 to Bellevue Way
112th SE Bypass Alternative (B3)	I-90 to Bellevue Way; SE 8th Street to I-405
B3 - 114th Extension Design Option	I-90 to Bellevue Way; 112th Avenue SE to the commercial area
BNSF Alternative (B7)	I-90 to I-405/118th Avenue SE
Segment C	
Preferred 108th NE At-Grade Alternative (C11A)	112th Avenue SE at Main Street; Main Street and 108th Avenue NE (all connections); 108th Avenue NE and NE 6th Street; NE 6th Street to the former BNSF Railway corridor; south of the Hilton Hotel under B3 - 114th Extension Design Option
Preferred 110th NE Tunnel Alternative (C9T)[a]	112th Avenue SE at Main Street (all connections); NE 6th Street to the former BNSF Railway corridor; south of the Hilton Hotel under B3 - 114th Extension Design Option
Bellevue Way Tunnel Alternative (C1T)	NE 6th Street to the former BNSF Railway corridor
106th NE Tunnel Alternative (C2T)	Main Street (connecting from Alternatives B2A, B3, and B7); NE 6th Street to the former BNSF Railway corridor
108th NE Tunnel Alternative (C3T)	Main Street (connecting from Alternatives B2A, B3, and B7); 112th Avenue NE at NE 12th Street
Couplet Alternative (C4A)	Main Street (connecting from Alternatives B2A, B3, and B7); Main Street and 110th Avenue NE; Main Street and 108th Avenue NE; NE 12th Street and 110th Avenue NE; NE 12th Street and 108th Avenue NE; 112th Avenue NE along NE 12th Street
112th NE Elevated Alternative (C7E)	112th Avenue NE along NE 12th Street (all connections); t112th Avenue SE south of Main Street (connecting from Alternatives B3 and B7)
110th NE Elevated Alternative (C8E)	114th Avenue NE to NE 2nd Street; NE 2nd Street to 108th Avenue NE; 108th Avenue NE to NE 12th Street; 112th Avenue NE along NE 12th Street (all connections)
110th NE At-Grade Alternative (C9A)	Main Street from 112th Avenue SE; Main Street to 108th Avenue NE; 108th Avenue NE to NE 6th Street; NE 6th Street to the former BNSF Railway corridor south of the Hilton Hotel under B3 - 114th Extension Design Option
114th NE Elevated Alternative (C14E)	I-405 at NE 7th Street; NE 7th Street to the former BNSF Railway corridor; South of the Hilton Hotel under B3 - 114th Extension Design Option
Segment D	
Preferred NE 16th At-Grade Alternative (D2A)[b]	BNSF Railway corridor to NE 16th Street; NE 16th Street to 134th Avenue NE; 134th Avenue NE to SR 520
D2A – NE 24th Design Option	BNSF Railway corridor to NE 16th Street; NE 16th Street to 134th Avenue NE; 134th Avenue NE to SR 520; NE 24th Street to 152nd Avenue NE; 152nd Avenue NE to SR 520
NE 16th Elevated Alternative (D2E)	BNSF Railway corridor to NE 16th Street; NE 16th Street to 134th Avenue NE; 134th Avenue NE to SR 520; NE 24th Street and 152nd Avenue NE; 152nd Avenue NE and SR 520
NE 20th Alternative (D3)	BNSF Railway corridor to NE 16th Street; NE 16th Street to 134th Avenue NE; 134th Avenue NE and NE 20th Street; NE 20th Street and 152nd Avenue NE; 152nd Avenue NE and SR 520
SR 520 Alternative (D5)	NE 12th Street (connecting from Alternatives C3T, C4A, C7E, and C8E); two curves between NE 16th Street and SR 520; 152nd Avenue NE; 152nd Avenue NE to SR 520
Maintenance Facilities	All Alternatives
Segment E	
Preferred Marymoor Alternative (E2)	SR 520 and Redmond Way

TABLE 4.7-7 CONTINUED
Summary of Curves with Potential Wheel Squeal

Alternative	Curves with Radius of 600 Feet or Less
E2 - Redmond Transit Center Design Option	SR 520 and Redmond Way; 161st Avenue NE to the Redmond Transit Center
Redmond Way Alternative (E1)	SR 520 to the elevated structure; Redmond Way; former BNSF Railway corridor
Leary Way Alternative (E4)	“S” curves from SR 520 to Leary Way; Leary Way to the former BNSF Railway corridor
Maintenance Facilities	All alternatives

[a] Curves with the C9T – East Main Station Design Option would not differ from *Preferred Alternative C9T*
[b] Curves with the D2A – 120th Station Design Option would not differ from *Preferred Alternative D2A*

TABLE 4.7-8
Summary of Potential Vibration Impacts

Alternative	Connection Alternatives	Before Mitigation		After Mitigation	
		Number of Vibration Impacts[a]	Number of Groundborne Noise Impacts[b]	Number of Vibration Impacts	Number of Groundborne Noise Impacts[b]
Segment A					
Preferred Interstate 90 Alternative (A1)	N/A	None	25 single-family	None	None
Segment B

114th NE Elevated Alternative (C14E)	B3 and B7	3 hotels	None	1 hotel	None
Segment D					
All alternatives	N/A	None	None	None	None
Segment E					
Preferred Marymoor Alternative (E2)[d]	N/A	3 single-family	None	1 single-family	None
Redmond Way Alternative (E1)	N/A	3 single-family	None	1 single-family	None
Leary Way Alternative (E4)	N/A	1 single-family, 1 multifamily, 1 hotel	None	None	None

[a] Commercial and industrial buildings are only assessed for vibration impact if they contain vibration-sensitive uses.
[b] Groundborne noise is only assessed for tunnel locations.
[c] Impacts for B3 – 114th Extension Design Option would not vary from those of Alternative B3.
[d] Impacts for E2 - Redmond Transit Center Design Option would not vary from those of *Preferred Alternative E2*.

In Table 4.7-8, the columns for the number of vibration and groundborne noise impacts refer to the number and type of buildings where vibration or groundborne noise impact is projected to occur. The number of units for multifamily buildings is provided, although it is likely that not all units would be affected. For multifamily buildings, the actual number of units impacted in each building would be determined after further testing during final engineering and design.

All impacts identified in the sections below are related to the proximity of the proposed tracks to individual buildings and to the speed of the light rail vehicle. In most cases, the impacts would be limited to buildings within 50 feet of the proposed tracks.

Potential vibration and groundborne noise levels and impacts reported in this section are described prior to mitigation considerations. Although most impacts can be mitigated, the residual impacts remaining after mitigation are provided in Table 4.7-8. Detailed information and exhibits for each impact are located in Appendix H2.

Segment A

At the East Link Project connection with the Central Link light rail system, there will be four new switches introduced to allow trains to operate on both light rail systems. These would be located under residential and mixed-use buildings. In order to keep vibration levels the same as from Central Link system operations, special trackwork would be needed at this location.

Under *Preferred Alternative A1*, groundborne noise impacts would occur at 25 single-family residences above the Mount Baker Ridge Tunnel. These impacts would occur because high-frequency vibration travels easily through the ground in this area.

Segment B

Under *Preferred Alternative B2M*, there would be no vibration impacts and only one groundborne noise impact (at the Winters House). The Winters House is no longer used as a residence and is occupied by the Eastside Heritage Center; therefore, it is considered a Category 3 land use—an institutional land use with primarily daytime use—for purposes of vibration and groundborne noise analysis. The FTA impact criteria for groundborne noise, measured in weighted decibels (dBA), are 40 dBA. A groundborne noise impact is projected at the Winters House because of the proximity of the alignment to the foundation of the building. The projected groundborne noise levels would range from 44 to 54 dBA.

For the Winters House, the operational vibration levels, measured in VdB, are projected to be 76 VdB, which would be below the FTA detailed impact criteria of 78 VdB for human annoyance. In addition, the projected operational vibration levels would be well below even the most stringent criteria for damage to structures, which is 90 VdB for buildings extremely susceptible to vibration. The Winters House is in a slightly less susceptible category, which is for nonengineered timber and masonry buildings, with a 94 VdB criteria for damage.

Under *Preferred Alternative B2M* with the C9T – East Main Station Design Option, there would be one vibration impact at a single-family residence due to the relocated crossover at SE 8th Street, as well as the same groundborne noise impact at the Winters House as described in the previous paragraphs.

Under all other Segment B alternatives, the only vibration impact would be to a single-family residence with Alternative B1. This impact would occur because of the proximity of the residence to the track and because high-frequency vibration travels easily through the ground in this area.

Segment C

The vibration impacts in Segment C would result from the proximity of the proposed alternatives and the speed of the light rail vehicles.

In addition to the residential land uses in this corridor, vibration and groundborne noise impacts were also assessed for the special sensitive receptors in this segment, including the Bellevue Arts Museum, the theater in Meydenbauer Center, the Overlake Hospital MRI Unit, the Overlake Hospital Optical Surgery Unit, as well as the MRI unit at the Group Health Medical Center. The results of the vibration analysis at these locations indicated there is no projected impact at the hospitals and MRI units. Details regarding the groundborne noise and vibration levels at these sensitive sites are included in Tables 4-2, 4-3, 4-4, and 7-3 of Appendix H2.

Under *Preferred Alternative C11A*, there would be vibration impacts at two single-family residences, three multifamily buildings, and one hotel.

Preferred Alternative C9T would result in vibration impacts at seven single-family residences and one hotel. Five of the single-family residential impacts would be due to the crossover on 112th Avenue SE. In addition, there would be a groundborne noise impact at the Meydenbauer Center. Under the C9T – East Main Station Design Option, the replacement of this crossover with the East Main Station would reduce the vibration impacts to two single-family residences and one hotel. The groundborne noise impact at the Meydenbauer Center would also still occur as described above under *Preferred Alternative C9T*.

Alternatives C2T connecting from B2A, B3, and B7, and Alternative C7E would not have any projected vibration impacts. All the other Segment C alternatives would have vibration impacts, with the greatest number of impacts occurring with Alternatives C4A, C8E, or C9A. The impacted structures would be mixed use buildings that have ground floor commercial uses with multifamily residences above. The distance to sensitive uses in these buildings might eliminate these impacts.

Segment D

No vibration impacts are projected for Segment D, including at the Children's Hospital BCSC medical facility.

Segment E

Preferred Alternative E2 would result in vibration impacts on three single-family residences. These vibration impacts would result because high-frequency vibration would travel easily through the ground in this area and because of the track's proximity to the residences. These impacts would also occur with the E2 - Redmond Transit Center Design Option.

For the other Segment E alternatives, vibration impacts would occur at three single-family residences with Alternative E1. Alternative E4 would have vibration impacts on one single-family residence, one multifamily building, and one hotel. These vibration impacts would be due to the proximity of the residences and because high-frequency vibration travels easily through the ground in this area.

Maintenance Facilities

Maintenance facility alternatives are not expected to result in any vibration impacts.

4.7.3.5 Impacts during Construction

This section summarizes potential construction noise and vibration impacts. More detailed information is provided in Appendix H2.

Noise

Noise related to construction would result from the operation of heavy equipment needed to construct the project. State and local ordinances regulate construction noise, and the contractor would be required to adhere to these regulations. This section provides a general understanding of average and worst-case noise levels from construction. Because of the varying types of construction activities, the location of noise-sensitive properties, distances from construction sites and staging areas to noise-sensitive properties, and other construction-related variables, it is not possible to provide exact construction noise levels.

The primary construction noise regulations are found in the WAC. The state provisions have been adopted, in some form, by most cities and counties around the state, including the Cities of Seattle, Bellevue, and Redmond. No specific construction noise ordinance was identified for Mercer Island, and therefore the Washington State construction ordinance would also be the governing criteria for construction activities on the island. Information in the WAC, which outlines the specific construction regulations for most locations, is provided below, followed by a construction noise analysis.

Sound Transit would, as practical, limit construction activities that produce the highest noise levels to daytime hours, or when disturbance to sensitive receivers would be minimized.

Contractors would be required to meet the criteria of the noise ordinance for the city within which they are working. Construction outside normal weekday hours (i.e., 7 a.m. to 10 p.m. for locations governed by the WAC) may require a noise variance from the city or county where the work is being performed. For example, the City of Bellevue only exempts construction noise from 7 a.m. to 6 p.m. on weekdays, and from 9 a.m. to 6 p.m. on Saturdays, so any major construction activities outside these hours in the City of Bellevue would require a noise variance.

It is also important to note that unlike the light rail noise analysis, which uses the Ldn and Leq for impact assessment, the WAC and other construction noise ordinances use several other noise metrics in addition to the Ldn and Leq. Instantaneous sound pressure levels in dBA (SPL in dBA), maximum 1-second noise levels in dBA (Lmax), and statistical noise descriptors are all terms that are used to ensure compliance with the WAC. Finally, because of possible restrictions on daytime construction along major arterials (because of traffic disruptions), it is likely that at least some construction along major corridors could occur during nighttime hours. Under alternatives with bored tunnels, it is likely that that the tunnel portals could operate 24 hours per day, and up to 7 days per week. Due to the WAC and local noise control regulations, work outside the allowable hours would require obtaining a noise variance from the local jurisdiction.

Listed below are allowable noise exceedances (referred to "as exempt") for general construction equipment, haul trucks, and alarms, as provided in the WAC.

- **General Equipment:** For construction activities, the limits in Table 4.7-3 may be exceeded between 7 a.m. and 10 p.m. on weekdays, and 9 a.m. and 10 p.m. on weekends, as shown in Table 4.7-4.
- **Haul Trucks:** Noise from haul trucks is exempt when operating on public roadways. Maximum permissible sound levels for haul trucks at the construction site are limited to 86 dBA for speeds of 35 mph or less and 90 dBA for speeds over 35 mph.
- **Alarms:** Sounds created by back-up alarms are exempt when operated for less than 30 minutes per incident.

Project Construction Phases

Several construction phases would be required to complete the East Link Project. This analysis assumes the worst-case noise levels based on three major construction phases, further defined in Table 4.7-9:

- Demolition, site preparation, and utility relocation
- Structure construction, track installation, and paving
- Miscellaneous activities

The actual noise levels experienced during construction would generally be lower than those presented in this section and in Table 4.7-9. The noise levels discussed here (and presented in Table 4.7-9) are for periods of maximum construction activity and are considered worst-case for the major phases of construction, measured at a distance of 50 feet from the construction site. Residential and commercial land uses are most sensitive to construction noise.

General Construction

In Segments B through E, constructing elevated guideways, at-grade trackways, tunnels, stations, and tunnel portals would increase the amount of truck traffic near construction staging areas. Haul truck and delivery truck volumes and times of travel would vary depending on the specific site activities occurring at any one time.

The highest levels shown in Table 4.7-9 would be experienced during the heaviest construction periods. Noise levels would be 5 to 15 dBA lower than the highest levels during minor construction work, such as finishing work and system installation. Constructing bridges and elevated structures might require pile driving, which could produce maximum noise levels of 99 to 105 dBA Lmax at 50 feet from the work site. Actual levels can vary and would depend on the distance and topographical conditions between the pile-driving location and the receiver location. Pile driving might be required in Segments B, C, D, and E for the elevated profiles and might also occur in areas of retained cuts in Segments C and D. Pile driving would be required to meet the WAC impact criteria. Following are segment-specific discussions related to construction noise.

Segment A

In Segment A under *Preferred Alternative A1*, most construction activities would occur during weekday daytime hours in the I-90 corridor, which is some distance from commercial and residential uses. Noise from construction could reach 75 to 78 dBA Lmax because of the distance between the construction and noise-sensitive properties and shielding from the retaining walls along I-90, and no impacts are expected.

Segment B

Preferred Alternative B2M and most other Segment B alternatives consist of a combination of elevated, retained cut, retained fill, and at-grade track types; therefore, the construction techniques for each alternative would be very similar. The main differences would be long-term fixed-site construction, such as those associated with the tunneling alternatives, compared with moving operations, such as paving, at-grade track construction, and elevated structure installations.

Under the Segment B alternatives single- and multifamily residences and several businesses could be affected by construction noise. Under *Preferred Alternative B2M* and Alternatives B1, B2A, B2E, and B3, adjacent properties would experience maximum noise levels exceeding 80 dBA Lmax for short periods, assuming that these properties are 100 to 125 feet from the construction activity. Construction noise would occur when relocating utilities, installing retaining walls (where required), constructing the lidded retained cut at the Winters House under *Preferred Alternative B2M*, repaving Bellevue Way SE, and constructing the elevated guideways for *Preferred Alternative B2M* and Alternatives B2A, B2E, B3, and B7. Noise levels would be greatest for properties adjacent to Bellevue Way SE and near the elevated segments on I-90, but would be less for those located along 112th Avenue SE, where residences and business parks are set back farther from the project corridor in many places. During construction of elevated structures, noise from pile driving could produce Lmax noise levels of 98 to 105 dBA Lmax at 50 feet from the work site.

With Alternative B7, noise levels at the multifamily apartments and condominiums adjacent to the former BNSF Railway corridor could reach 80 dBA Lmax for short periods. Because this alternative is not on a major roadway, it is unlikely that nighttime work would be required near the noise-sensitive units. Construction of Alternative B7 would also increase noise at some commercial buildings;

In Segment B, construction noise would be exempt if performed between 7:00 a.m. and 6:00 p.m. Monday through Friday, and between 9:00 a.m. and 5:00 p.m. on Saturdays. Construction during all other hours would require authorization from the applicable Bellevue department director, consistent with the criteria set out in the City of Bellevue noise ordinance

TABLE 4.7-9
Maximum Noise Levels for Typical Construction Phases at 50 Feet from the Work Site

Scenario[a]	Equipment[b]	Lm[c]	Leq[d]
Demolition, site preparation, and utility relocation	Air compressors, backhoe, concrete pumps, crane, excavator, forklifts, haul trucks, loader, pumps, power plants, service trucks, tractor trailers, utility trucks, vibratory equipment	94	87
Structure construction, track installation, and paving	Air compressors, backhoe, cement mixers, concrete pumps, crane, forklifts, haul trucks, loader, pavers, pumps, power plants, service trucks, tractor trailers, utility trucks, vibratory equipment, welders	94	88
Miscellaneous activities	Air compressors, backhoe, crane, forklifts, haul trucks, loader, pumps, service trucks, tractor trailers, utility trucks, welders	91	83

Note: Combined worst-case noise levels for all equipment at a distance of 50 feet from work site.
[a] Operational conditions under which the noise levels are projected.
[b] Normal equipment in operation under the given scenario.
[c] Lm (dBA) is an average maximum noise emission for the construction equipment under the given scenario.
[d] Leq (dBA) is an energy average noise emission for construction equipment operating under the given scenario.

Segment C

In Segment C, the longest period of high-intensity construction activities would occur at cut-and-cover tunneling sites and bored tunnel staging areas. Maximum noise levels exceeding 80 dBA Lmax, assuming a distance of 100 to 125 feet from the construction activity, could occur during periods of heavy construction activity. Noise levels would be highest during periods of spoil hauling, when noise levels from haul trucks would be the dominant noise source, with maximum noise levels of 86 dBA Lmax at 50 feet. *Preferred Alternative C9T* would require such a staging area near the portals at Main Street, along NE 6th Street, and on 110th Avenue NE between NE 3rd Place and NE 2nd Place. Under *Preferred Alternative C11A*, staging areas would still be required; however, the level of activity at staging areas for the at-grade profile would typically be less intense than those for tunnels.

Noise levels near the tunnel portals and at-grade alignments along 112th Avenue SE and Main Street with *Preferred Alternatives C11A* and *C9T*, and Alternatives C2T, C3T, C4A, C7E, and C9A, and on Bellevue Way for Alternative C1T, could exceed 80 dBA Lmax at nearby residences during heavy construction periods. Noise levels near the tunnel portals and construction areas during general construction activities are predicted to range from 73 to 84 dBA Lmax at 50 feet from the work site. Similar levels are projected along NE 6th Street with *Preferred Alternative C9T* and Alternatives C1T and C2T. Staging areas along NE 12th Street and McCormick Park for Alternatives C3T, C4A, and C8E would also experience similar noise levels. To construct elevated structures along 112th Avenue NE under Alternative C7E and along 110th Avenue NE under Alternative C8E, maximum noise levels would range from 80 to 85 dBA Lmax at 50 feet from the project construction area. Constructing the light rail along NE 12th Street would increase noise levels at Overlake Hospital. The hospital parking garage would provide shielding for some patient rooms. Construction noise under the other two at-grade alternatives (C4A and C9A) would be similar to those described for *Preferred Alternative C11A*, although Alternative C4A would occur along 108th Avenue NE and 110th Avenue NE, and Alternative C9A would occur only along 110th Avenue NE.

As previously described for Segment B, construction noise in Segment C would be exempt if performed between 7:00 a.m. and 6:00 p.m. Monday through Friday, and between 9:00 a.m. and 5:00 p.m. on Saturdays. Construction during all other hours would not be exempt under the City of Bellevue noise ordinance, and would require a noise variance.

Segment D

In Segment D, *Preferred Alternative D2A* and the other alternatives would produce construction-related noise levels similar to those already discussed in Segments B and C. In Segment D, however, there are fewer residences; therefore, construction noise is not expected to impact as many residences as in Segments B or C.

Constructing the at-grade and elevated profiles through Segment D would result in short-term high noise levels at commercial and retail structures located along the corridor. Constructing the light rail along NE 12th Street would increase noise levels at the Children's Hospital BCSC. Levels would increase to the levels listed in Table 4.7-9 when construction activities are near these properties and would decrease as the activities move away.

Commercial and retail land uses along the proposed corridors would experience maximum noise levels of 80 dBA Lmax, assuming 100 to 125 feet from the construction activity. Constructing Segment D along the south and east shoulder of SR 520 would also increase construction noise and traffic east of 140th Avenue NE to the Segment E connection, depending on the alternative selected. In this area, maximum construction noise levels of 91 to 94 dBA Lmax can be expected for short periods, with typical hourly average noise levels ranging between 70 and 80 dBA Lmax at 50 feet.

Because Segment D is situated in Bellevue and Redmond, two construction noise regulations would apply. In this type of situation, the contract specifications typically would use the most stringent regulations in most areas to ensure compliance. Therefore, in most areas construction noise would be exempt if performed between 7:00 a.m. and 6:00 p.m. Monday through Friday and between 9:00 a.m. and 5:00 p.m. on Saturdays. However, in the Overlake area, it might be possible for work to continue later in the day because the WAC regulations allow for construction until 10:00 p.m. on weekdays.

Segment E

Constructing *Preferred Alternative E2*, and the other Segment E alternatives along the shoulder of SR 520 from NE 40th Street to West Lake Sammamish Parkway NE, could result in relocating sound walls along the single-family residential area along 156th Avenue NE. During that time, construction noise and traffic would increase for the residential area north of NE 51st Street to maximum noise levels exceeding

80 dBA Lmax, assuming 100 to 125 feet from the construction activity.

Constructing the elevated structures and at-grade profiles would elevate noise levels at the multifamily units along West Lake Sammamish Parkway NE, 156th Place NE, and along Leary Way NE because Alternatives E1 and E4 would require using heavy construction in this immediate area. Pile driving for the Sammamish River crossing for all alternatives and along Leary Way NE for Alternative E4 could result in peak levels exceeding 100 dBA Lmax. In Downtown Redmond, construction noise would be prevalent along the former BNSF Railway corridor under all Segment E alternatives. Constructing the E2 - Redmond Transit Center Design Option would increase noise levels along 161st Avenue NE.

Maintenance Facilities
Construction of the potential maintenance facility alternatives located in Segment D (MF1, MF2, and MF3) could have some impact on adjacent properties. MF1 would have the most likelihood of noise impacts during construction because it is located near several single-family residences and the Children's Hospital BCSC. The MF2 and MF3 maintenance facility alternative sites are located in primarily industrial and commercial areas, which are generally less sensitive to construction noise levels. MF5 would be in an area of primarily commercial use and high existing noise levels, reducing the potential for construction noise impacts.

Vibration

Construction vibration, similar to noise, is highly dependent on the specific equipment and methods employed. Construction vibrations cause a variety of potential effects, ranging from influence on vibration-sensitive equipment and low rumbling or groundborne noise at lower levels, perceptible human vibrations at moderate levels, and potential slight damage to buildings at the highest levels. Generally, construction vibrations are assessed at locations where prolonged annoyance or damage would be expected.

In most cases, the main concern for construction vibration is potential damage to structures. Most construction processes do not generate high enough vibration levels to approach damage criteria. The thresholds for building damage are 1 to 2 orders of magnitude higher than criteria for annoyance. Because construction is a short-term, temporary impact, the potential for structural damage is considered more critical than the potential for annoyance. The only time annoyance is usually addressed for construction vibration is for longer-term impacts, such as those related to the tunneling in Segment C. However, the thresholds for annoyance from construction vibration are substantially lower than those for damage to structures.

The major sources of construction vibration include impact pile driving, augered piling, vibratory rollers, and tunnel boring machines, including associated muck trains. The only project activity with potential to cause building damage is impact pile driving at locations within 25 feet of structures. The Coast Bellevue Hotel is the only structure within 25 feet of *Preferred Alternative C9T* and Alternative C9A. If pile driving were performed at this location, there would be the potential for damage.

There are many alternatives to impact pile driving, including sonic pile driving, and augered or drilled pile construction. Specific locations of piling would not be available until final design, but would likely include locations of elevated structures or retained cuts approaching tunnels. As specific locations of piles are developed, more analysis would be conducted to assess specific impacts. To prevent damage, care would be taken not to pile drive too close to buildings.

Constructing a retained cut near the Winters House, including construction of underground piles to structurally support the cut, could result in vibration impacts. Because of the property's age and type, damage to the building could occur without construction vibration-minimization techniques. The criteria for damage for this type of structure are 94 VdB or 0.2 peak particle velocity (PPV); construction vibration is projected to be 0.2 PPV. Using the techniques and construction methods described below as mitigation would prevent vibration damage or limit damage to minor cosmetic damage. For a discussion of vibration descriptors and damage criteria, refer to Sections 2.2 and 4.5 in Appendix H2.

In order to assess the potential for annoyance from construction vibration, vibration levels for impact pile driving, vibratory rolling, tunneling and muck trains were predicted for the ground floors inside buildings using conservative assumptions. These assumptions include no coupling attenuation (i.e., reduction in vibration levels due to the foundation of the building) for single-family residences, a 10-decibel building coupling attenuation for large masonry buildings, and no floor-to-floor attenuation. The criteria used to assess construction vibration and groundborne noise are the same as those used to assess transit operation impacts.

Table 4.7-10 shows the typical distances at which groundborne vibration annoyance would occur for both single-family residences and large masonry buildings for each piece of construction equipment. The only locations where impacts from tunnel boring and muck trains could occur would be in the tunnel alternative segments. Impacts from pile driving would only occur at locations where piling is planned.

TABLE 4.7-10
Typical Distances from Sources to Vibration and Groundborne Noise Impact

Construction Equipment	Distance to Groundborne Vibration Impact (feet)	Distance to Groundborne Noise Impact (feet) [a]
Tunnel-boring machine in soil (large masonry buildings)	6	7
Tunnel-boring machine in soil (single-family residences)	13	14
Muck trains (large masonry buildings)	8	24
Muck trains (single-family residences)	16	51
Vibratory roller (large masonry buildings)	18	N/A
Vibratory roller (single-family residences)	36	N/A
Impact pile driving (large masonry buildings)	70	N/A
Impact pile driving (single-family residences)	150	N/A

[a] Groundborne noise is only assessed for tunnel locations.

At all other locations, the vibration generated by construction activities would be minimal. However, most activities would be far enough away from buildings that there would not be any impacts.

It is important to note that these are temporary impacts, and the annoyance from these activities would be very limited in duration. For most activities, including tunneling, the duration would be only a few days to a few weeks for each activity. The only activity with a longer duration would be the muck trains near the portals of the tunnels, which could be running between 1 month and 18 months, depending on the tunnel alternative chosen and the speed of tunneling. Sound Transit's experience in monitoring vibration during tunneling on Central Link has found no vibration impacts associated with annoyance to residences throughout the length of the tunnel.

For more information on construction vibration, refer to Appendix H2.

4.7.4 Station Platform Noise Levels

Because of the unique setting of several stations in proximity to major freeways, Sound Transit modeled potential noise levels at proposed station platforms where light rail patrons might be exposed to noise from heavy freeway traffic volumes. These stations included the Rainier, Mercer Island, and Ashwood/ Hospital stations, which are all located within or above a major freeway. The proposed East Link operations plan would result in a typical maximum of 15 minutes between train arrivals at any of these stations, and therefore 15 minutes would typically be the longest period patrons would be exposed to noise while waiting for trains to arrival. Although it is possible that a patron could wait up to 15 minutes or more (if trains are running late), the Leq over a 20-minute period is expected to be the same as for a 15-minute period because of the steady-state nature of traffic along SR 520.

There are no federal standards for noise exposure on transit passengers at station platforms due to traffic noise. The National Institute for Occupational Safety and Health (NIOSH) standard for workplace noise exposure is 85 dBA for up to 8 hours, or 100 dBA for 15 minutes (NIOSH, 1998). The U.S. Environmental Protection Agency (EPA) states that communication at close proximity (2 to 4 feet) can be understood with ambient noise levels of 72 to 78 dBA (EPA, 1974). For contextual comparison, Sound Transit measured noise levels at two existing flyer bus stops located adjacent to heavy freeway traffic. Existing noise levels at the Rainer I-90 flyer stop were measured at 76 dBA Leq, while the typical existing noise level at the SR 520 flyer stop at Montlake was 81 dBA Leq. Based on these standards and existing bus flyer stop noise levels, Sound Transit will use a 78 dBA 15-minute Leq platform noise level goal for designing stations within or above freeways, where reasonable and feasible.

During peak noise hours, station patrons may experience noise levels ranging as high as 85 to 86 dBA at the Rainier Station and 88 dBA at the Mercer Island Station. The higher noise levels on Mercer Island are due to the highway's retained cut and traffic noise being reflected around the station platform off the adjacent retaining walls. Sound Transit would consider including noise-reducing sound walls between the tracks and I-90 traffic lanes for both stations. Modeling sound walls for each station shows that they would reduce noise levels by approximately 8 to 10 dBA on the platform, bringing the station platform noise at both sites to within Sound Transit's station platform design goal of

78 dBA. Complete details on the station analysis are provided in Appendix H2.

4.7.5 Potential Mitigation Measures

4.7.5.1 Noise Mitigation During Operation

Sound Transit is committed to minimizing noise levels at the source. This includes using only state-of-the-art vehicles equipped with wheel skirts to reduce noise. In addition, Sound Transit has committed to a maintenance program that includes periodic rail grinding or replacement, wheel truing or replacement, vehicle maintenance, and operator training, which all help to reduce noise levels along transit corridors. For noise impacts that still exist after these source noise treatments, noise mitigation measures would be provided that are consistent with Sound Transit's Light Rail Noise Mitigation Policy (Motion No. M2004-08). The FTA manual also defines when mitigation is needed and bases this on the impact's severity, with severe impacts requiring the most consideration. During final design, all impacts and mitigation measures will be reviewed for verification. During final design, if it is discovered that mitigation can be achieved by a less costly means or if the detailed analysis show no impact, then the mitigation measure may be eliminated or modified.

The mitigation proposed below follows Sound Transit policy. Table 4.7-6 summarizes potential project light rail and traffic noise mitigation for each alternative.

Transit Noise Mitigation

The potential mitigation options available for noise from transit operations on the East Link Project are primarily sound walls, special trackwork, lubricated curves, and residential building sound insulation. Sound walls are proposed where feasible and reasonable, as determined by Sound Transit based on specific site conditions. Sound walls would be located on the ground for at-grade profiles and on the guideway structure for elevated profiles. Sound walls are preferred because they are effective at reducing noise. For locations where there is a potential for traffic noise to be reflected off the sound walls, Sound Transit would propose to use absorptive treatments to remedy this issue.

A crossover track uses a frog (a rail-crossing structure) to allow the train to either cross over to another track or continue moving on the same track. A gap is provided on top of the frog so that vehicle wheels can pass regardless of which track is in use. With typical frogs, noise and vibration are generated when the wheels pass over the gap. Special trackwork, such as movable point or spring rail frogs, eliminates the gap between tracks at crossovers that causes noise and vibration at these locations.

Sound Transit is currently investigating the use of non-audible warnings for gated and ungated at-grade crossings. If non-audible warning devices are found to be viable, this option could be used to reduce or eliminate bell noise at specific crossings. Where practical, grade separation of at-grade light rail crossings would also be considered to eliminate the need for bells or other audible warning devices. If bells are used at gated crossings, the bells would be set at the minimum noise level that maintains a safe crossing. Finally, the use of acoustic bell shrouds would be examined during final design; the shrouds would direct the bell noise at gated crossings to the intersection.

When source mitigation measures or sound walls are infeasible or not entirely effective at reducing noise levels below the FTA impact criteria, then residential sound insulation would be evaluated and implemented at impacted properties where the existing building does not already achieve a sufficient exterior-to-interior reduction of noise levels. Many newer buildings, particularly in Downtown Bellevue, have good interior noise reduction and additional sound insulation may not be necessary.

Consistent with FTA methods and criteria, residential properties are considered "noise-sensitive" because people sleep there and "nighttime sensitivity to noise is assumed to be of utmost importance" (FTA, 2006). Accordingly, FTA analysis methods artificially increase measured existing noise and predicted project noise levels by 10 dBA (a perceived doubling of the noise level by most people) between 10:00 p.m. and 7:00 a.m. While noise measurements and impacts are analyzed at the exterior of residential properties, FTA methods clearly emphasize noise sensitivity for residential properties at night, because project noise could affect the ability of people to sleep. During the daytime hours, light rail noise levels are very similar to (in many cases less than) common noise levels in urban settings like Downtown Bellevue or along transportation corridors (like I-90, Bellevue Way, 112th Avenue SE, or I-405) where the predominant noise is from existing traffic (buses, trucks, and heavy traffic volumes). During those times of the day when outdoor uses are most frequent, noise from light rail would typically be less noticeable because of the higher ambient noise levels from traffic and other urban sources.

Traffic Noise Mitigation

Traffic noise impacts would be mitigated by sound walls, where determined to be reasonable and feasible.

For locations with residual traffic noise impacts caused by the project, sound insulation might also be considered by Sound Transit. Use of FHWA or WSDOT funds to insulate residences from sound for traffic noise abatement is allowed only in specific situations. Federal regulation 23 CFR 772.13(c)(6), and WSDOT and FHWA policies and procedures limit sound insulation for traffic noise abatement to public use or nonprofit institutional structures and only in situations where a barrier is ineffective, unreasonable, and/or infeasible and interior noise levels are above the impact criteria. Sound insulation of residences is allowed only when noise impacts are severe (i.e., above 80 dBA exterior or above 60 dBA interior) and no other type of abatement is possible. In contrast, Sound Transit considers residential sound insulation for any noise impacts related to light rail projects if a sound wall is ineffective, unreasonable, and/or infeasible.

Segment A

In Segment A, the only potential noise impact resulting from *Preferred Alternative A1* would be near the transition from the Mount Baker Ridge Tunnel to the floating bridge structures. A light rail expansion joint would be required to allow for bridge movement; as a result, increased noise related to this joint could occur. If, after testing of the expansion joint prototype, the expansion joint near the Mount Baker Ridge Tunnel were determined to cause a noise impact, then mitigation would likely be a short, absorbent sound wall along the structure's side or absorbent material applied to the existing traffic safety barriers.

To reduce noise levels on the Rainier Station and Mercer Island Station platforms, Sound Transit would incorporate design measures to reduce freeway noise for patrons waiting at station platforms.

Segment B

In Segment B, mitigation measures under *Preferred Alternative B2M* when connecting to *Preferred Alternative C11A* would include a sound wall running continuously from the elevated section on I-90 to the retained cut section south of the Winters House along Bellevue Way SE. North of the 112th Avenue SE intersection, a sound wall is proposed at-grade, along the west side of the guideway, to just south of the Bellefield Residential Park Condominiums. A new sound wall would start along the west side of 112th Avenue SE and continue to the Segment C connection. The second sound wall would need to overlap with the first wall and would be effective at reducing traffic noise at the Bellefield Residential Park Condominiums. Openings in the wall would be required for vehicle and pedestrian access to the Bellefield Residential Park Condominiums, reducing the overall effectiveness. Supplemental sound insulation might also be required at six multifamily and four single-family residences.

Noise mitigation for *Preferred Alternative B2M* when connecting to *Preferred Alternative C9T* would be identical to *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* south of 112th Avenue SE. A second wall would be installed just north of the 112th Avenue SE intersection, on the west side of the guideway, to just north of the SE 8th Station. Openings would be required for pedestrian and vehicle access at SE 15th Street and SE 8th Street. Special trackwork would also be used for the crossovers. Up to ten residences along 112th Avenue SE might also be provided with sound insulation to complete the noise mitigation measures if the sound walls are not effective at mitigating all impacts.

Impacts under *Preferred Alternative B2M* connecting to C9T – East Main Station Design Option would be similar to *Preferred Alternative B2M* connecting to *Preferred Alternative C9T*; therefore, the proposed mitigation would be similar to that described above for *Preferred Alternative B2M* to *Preferred Alternative C9T*.

For the other Segment B alternatives, a combination of sound walls and sound insulation would be used to mitigate impacts, except for Alternative B7, where all impacts could be mitigated with sound walls. In addition, all crossovers near noise-sensitive properties would include special trackwork to mitigate crossover-related impacts.

There are several locations along Bellevue Way under Alternative B1 where sound walls would block local access, and therefore sound insulation might be considered as the primary mitigation measure. Under Alternatives B2A, B2E, and B3 (including the B3 - 114th Extension Design Option), sound walls would be installed beginning at I-90 and continue past the South Bellevue Park-and-Ride. Under Alternative B2E, the walls would be continuous through to Segment C. Under Alternatives B2A and B3, the walls would end just south of 112th Avenue SE, and several homes in along 112th Avenue SE would be treated with sound insulation. Sound walls would also be used north of the 112th Avenue SE intersection, continuing to Segment C under Alternative B2A, and with the elevated structure for Alternative B3 and the B3 - 114th Extension Design Option. There would be three sound walls along Alternative B7: one along I-90 near Bellevue Way SE, one at the multifamily units north of I-90 along 118th

Avenue SE, and one at a multifamily community near the former BNSF Railway corridor I-405 crossing.

Segment C

In Segment C under *Preferred Alternative C11A* from *Preferred Alternative B2M*, mitigation would include a sound wall along the west side of the alignment beginning near SE 6th Street and continue as a sound barrier to 108th Avenue NE, just south of Main Street. The wall would be located near the tracks on the retained fill and elevated structure to the 108th Station. The sound wall/barrier, along with special trackwork at the crossover along 112th Avenue SE, would mitigate all impacts along this section of the corridor. Sound walls and special trackwork for the crossover would also be used to mitigate impacts on the Coast Bellevue Hotel and Lake Bellevue Village Condominiums. Multifamily units located on Main Street, 108th Avenue NE, and NE 6th Street would be mitigated with sound insulation where necessary. Under connections from B3, B3 - 114th Extension Design Option, or B7, sound walls along the elevated structure would be used for mitigation.

Noise mitigation under *Preferred Alternative C9T* from *Preferred Alternative B2M*, would be similar to that proposed for *Preferred Alternative C11A* and would also include a sound wall along the west side of the alignment beginning near SE 6th Street continuing to the tunnel transition. The wall would likely be located on a retaining wall to the west of the tracks, with final placement determined during final design. This sound wall, along with special trackwork at the crossover along 112th Avenue SE, would mitigate all impacts along this section of the corridor. Sound walls and special trackwork at the crossover would also be used to mitigate impacts on the Coast Bellevue Hotel and Lake Bellevue Village Condominiums. Impacts located on SE 4th Street would be mitigated with a sound wall if possible, otherwise sound insulation would be employed for mitigation. Single- and multifamily units located on Main Street and NE 6th Street would be mitigated with sound insulation where necessary. Under connections from B3, B3 - 114th Extension Design Option, or B7, sound walls along the elevated structure would be used for mitigation.

For the other Segment C alternatives, impacts from the elevated portions could be mitigated with sound walls, while the areas with at-grade profiles could require sound insulation. As with Segment B, crossover related impacts would be mitigated with special trackwork.

There are several traffic noise impacts under Alternative C1T on Bellevue Way that would likely receive sound insulation because sound walls would not be effective due to openings for driveways. Sound insulation would also be used for multifamily units in the Downtown Bellevue area. Finally, east of I-405, a combination of sound walls and special trackwork would mitigate the remaining impacts at the Coast Bellevue Hotel and the Lake Bellevue Village Condominiums. This same mitigation would be used for all alternatives following the same general alignment east of I-405, including Alternatives C2T, C9A, and C14E. Even though Alternative C14E runs north of the Coast Bellevue Hotel, sound walls and special trackwork would still be employed.

South of Main Street, all Segment C alternative connections from Alternatives B2A or B2E along 112th Avenue SE would provide mitigation with a combination of sound walls and special trackwork, except Alternatives C2T and C3T from B2A, which would be in a tunnel in this area. For connections from Alternatives B3, B3 - 114th Extension Design Option, and B7, mitigation would include sound walls along the elevated structures.

Through Downtown Bellevue and the central business district, at-grade alternatives would use sound insulation where existing buildings do not provide sufficient sound reduction because there is no other form of mitigation available for the high-rise residences. Elevated guideways in the same area would use sound walls as the primary form of mitigation. North of Downtown Bellevue along NE 12th Street, under Alternatives C3T, C4A, and C8E, a combination of sound walls, where practical, and sound insulation would be the recommended mitigation measures.

Segment D

There are no anticipated noise impacts for *Preferred Alternative D2A* or the D2A design options, so no noise mitigation is proposed.

For Segment D alternatives that connect to Segment C on NE 12th Street (i.e., Alternatives D2E, D3, and D5), the mitigation for the Children's Hospital BCSC impact would be a sound wall along the north side of the tracks. The impact on the Pacific Northwest Ballet School under Alternative D2E would be reviewed during final design because there are no apparent exterior uses at this facility. Based on a site visit, the interior areas of the building are expected to have noise levels compatible with a school, and additional mitigation may not be warranted. Under Alternative D5, a sound wall would be required near the multifamily units south of SR 520 for both the NE 12th Street and the former BNSF Railway corridor connections to Segment C.

Segment E

Noise mitigation for *Preferred Alternative E2* and the E2 - Redmond Transit Center Design Option would include sound walls along the elevated structures from SR 520, near NE 67th Place, to the at-grade transition by Marymoor Park. All remaining noise impacts would occur at high-rise apartments on Cleveland Street and a hotel on NE 76th Street. If necessary, sound insulation along with special trackwork for the crossover would be used to mitigate these impacts. Under the E2 - Redmond Transit Center Design Option, one of the buildings impacted under *Preferred Alternative E2* would no longer have noise impacts, however, a separate new multifamily building on 161st Avenue NE north of Redmond Way is predicted to have noise impacts, and would receive sound insulation for noise mitigation if necessary.

Alternatives E1 and E4 would both have a sound wall along the at-grade and retained fill transitions to an elevated structure near NE 67th Place. There would also be sound walls along the elevated structures as they transition to the at-grade profiles. All other noise impacts, including those along the former BNSF Railway corridor, would be mitigated with sound insulation. All crossovers would receive special trackwork to keep crossover noise to a minimum.

When Segment E is funded and the design is advanced, Sound Transit will evaluate potential noise impacts again at Marymoor Park, based on the uses in place at that time, consistent with FTA methods and criteria.

Maintenance Facilities

There are three maintenance facility alternatives in Segment D. MF1 is located near several single-family residences, a hospital, and several office buildings. Of the three Segment D maintenance facility options, MF1 has the highest potential for noise impacts. Because noise impacts were identified at the Children's Hospital BCSC, mitigation measures were evaluated for the MF1 site. Noise impacts would be mitigated through the installation of a sound wall approximately 12 feet in height along the southern part of the site. The proposed sound wall would mitigate the noise impact at the hospital. MF2 and MF3 are in established industrial areas and are not anticipated to result in any exceedance of the City of Bellevue noise control ordinance. During the facility design process, mitigation measures (such as lubricating rails on curves and locating compressors and other noise-producing sources in buildings or in a part of the facility that would be shielded from the residences) could be included in the design to ensure compliance with the City of Bellevue noise control ordinance. If necessary, a sound wall could also be installed along the site perimeter to block noise from affecting nearby noise-sensitive properties.

There is one maintenance facility alternative in Segment E. MF5 is in an established industrial area and is not anticipated to result in any exceedance of the City of Redmond noise control ordinance. During the facility design process, if noise impacts are identified, mitigation measures could be included in the design to ensure compliance with the City of Redmond noise control ordinance.

Wheel Squeal

For curves of 600-foot radius or less, a trackside or vehicle-mounted lubrication system would be used to mitigate wheel squeal noise. For curves of 600- to 1,000-foot radius, the project would be designed to accommodate a lubrication system if wheel squeal occurs during operations.

4.7.5.2 Construction Noise Mitigation Measures

As previously described, several different jurisdictions are responsible for the regulation of construction noise. In addition, most daytime construction activities would be exempt from the noise control ordinances. When required, Sound Transit or its contractor would seek the appropriate noise variance from the local jurisdiction. Sound Transit would control nighttime construction noise levels by applying noise level limits, established through the variance process, and use noise control measures where necessary. The contractor would have the flexibility of either prohibiting certain noise-generating activities during nighttime hours or providing additional noise control measures to meet these noise limits. Noise control mitigation for nighttime or daytime work may include the following measures, as necessary, to meet required noise limits:

- Install construction site noise barrier wall by noise-sensitive receivers.
- During nighttime work, use smart backup alarms that automatically adjust or lower the alarm level or tone based on the background noise level, or switch off back-up alarms and replace with spotters.
- Use low-noise emission equipment.
- Implement noise-deadening measures for truck loading and operations.
- Conduct monitoring and maintenance of equipment to meet noise limits.
- Use lined or covered storage bins, conveyors, and chutes with sound-deadening material.

- Use acoustic enclosures, shields, or shrouds for equipment and facilities.
- Install high-grade engine exhaust silencers and engine-casing sound insulation.
- Prohibit aboveground jack-hammering and impact pile driving during nighttime hours.
- Minimize the use of generators or use whisper quiet generators to power equipment.
- Limit use of public address systems.
- Use movable noise barriers at the source of the construction activity.
- Limit or avoid certain noisy activities during nighttime hours.

Pile driving might be required in Segments B, C, D, and E for construction of elevated profiles and bridges, and might also occur in areas of retained cuts in Segments C and D. To mitigate noise related to pile driving, the use of an augur to install the piles instead of a pile driver would greatly reduce the noise levels. If pile driving is necessary, the only mitigation would be to limit the time of day the activity can occur. Pile driving is not expected at most construction locations.

No segment-specific construction mitigation would be necessary for Segments A, B, or D during allowable daytime construction hours. In Segment C, at the tunnel staging areas near the Surrey Downs neighborhood and McCormick Park, a mitigation measure that could be used includes construction of temporary noise barriers adjacent to the construction staging area. Construction of Segment E alternatives along SR 520 near NE 51st Street could require moving existing sound walls and, if practical, these would be replaced early in project construction.

4.7.5.3 Vibration Mitigation During Operation

Vibration and groundborne noise impacts that exceed FTA criteria warrant mitigation when determined to be reasonable and feasible. The locations requiring mitigation in Table 4.7-8 would be refined during final design. At some locations, however, light rail trackways or guideways would be within 20 feet of buildings and vibration mitigation would not be effective at reducing the vibration level to below the FTA criteria. Exhibits 4.7-7 through 4.7-11 identify these locations as residual vibration impacts. At these locations, project design modification and additional information on affected buildings could eliminate these impacts. For instance, the type of building foundation might reduce vibration impacts and therefore, these residual impacts might be eliminated. In addition, each building would need to be examined in detail to determine where the vibration-sensitive uses are located. For example, the side of a building nearest the proposed alternative might be a vibration-sensitive use. Buildings that are mixed use might not have sensitive uses on lower floors where impacts would occur, and the vibration would not be noticeable by the time it reached higher floors with sensitive uses, such as sleeping quarters. Outdoor-to-indoor vibration testing, which tests how the vibration changes from the soil outside to a sensitive space inside a building, would also help to refine the vibration projections at these locations. A summary of segment-specific vibration mitigation is provided below.

Options for mitigating vibration impacts include the following:

- Install ballast mats, which consist of a pad made of rubber or rubberlike material placed on an asphalt or concrete base with the normal ballast, ties, and rail on top. The reduction in groundborne vibration provided by a ballast mat is strongly dependent on the vibration frequency content and the design and support of the mat.
- Use resilient fasteners to provide vibration isolation between rails and concrete slabs for direct fixation track typically on elevated structures or in tunnels. These fasteners include a soft, resilient element between the rail and concrete to provide greater vibration isolation than standard rail fasteners.
- Use tire-derived aggregate (TDA), which consists of shredded tires wrapped with filter fabric that is added to the base below the track ties.
- Install special trackwork, such as movable point or spring rail frogs, to eliminate the gap between tracks at crossovers that causes noise and vibration at these locations.
- Install floating slabs, which consist of thick concrete slabs supported by resilient pads on a concrete foundation; the tracks are mounted on top of the floating slab. Although floating slabs are designed to reduce vibration at lower frequencies than ballast mats, they are extremely expensive and are rarely used, except in the most extreme situations. Most successful floating slab installations are in subways, and their use for at-grade track is less common and often not reasonable.

In Segment A, approximately 1,900 feet of vibration mitigation would be required along the Mount Baker

Ridge Tunnel area to mitigate groundborne noise impacts at single-family homes along the top of the hillside. No other vibration impacts were identified in Segment A.

In Segment B, mitigation measures under *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* or *C9T* would include up to 600 feet of vibration isolation at the Winters House. Standard vibration mitigation methods, such as resilient fasteners or ballast mats, would reduce the groundborne noise level at the Winters House, but might not eliminate the impact and would be determined in final design. A floating slab might be needed to eliminate the groundborne noise impact. For *Preferred Alternative B2M* connecting to C9T – East Main Station Design Option, the crossover located at SE 8th Street would need to be relocated or special trackwork would need to be used to eliminate the gap due to the crossover. The only other vibration impact in Segment B would be with Alternative B1, where vibration mitigation would be required at one single-family residence near SE 13th Street.

In Segment C, under *Preferred Alternative C11A*, vibration mitigation would be required at two single-family residences south of Main Street, three multifamily structures along 108th Avenue NE, and the elevated structure by the Coast Bellevue Hotel. Under *Preferred Alternative C9T*, vibration mitigation would also be required at the same two single-family residences and the Coast Bellevue Hotel identified under *Preferred Alternative C11A*, along with five single-family residences near the crossover on 112th Avenue SE. These five single-family residential impacts could be eliminated by the relocation of the crossover or the use of special trackwork to eliminate the gap. Both *Preferred Alternatives C9T* and *C11A* identified groundborne noise impacts at the Meydenbauer Center, a highly sensitive location, where impacts would be mitigated using ballast mats or resilient rail fasteners. For the Alternative C9T – East Main Station Design Option, the impacts and required mitigation would be identical to that described above under *Preferred Alternative C9T*, except for the five single-family residences on 112th Avenue SE, which would not have vibration impacts under this design option because the crossover would be relocated to Segment B and replaced with the East Main Station.

Vibration mitigation under Alternative C1T would be included near the tunnel portal and tunnel segment along Bellevue Way for two single-family residences, and on the elevated structure for the Coast Bellevue Hotel. Under Alternative C2T mitigation would only be required at one single-family residence south of Main Street when connecting to Alternative B2E. No other vibration or groundborne noise impacts were identified under Alternative C2T.

With Alternative C3T, the connection to Alternative B2A would require mitigation for groundborne noise at 11 single-family residences. All of the impacts are located on top of the tunnel south of Main Street. Under the Alternative C3T connection to Alternatives B2E, B3 or B7, only one single-family residence, on the south side of Main Street, is identified as having a groundborne noise impact. Alternative C4A would require vibration mitigation for six multifamily residences and one single-family residence, regardless of the connection options. The multifamily noise impacts are along 108th and 110th Avenues NE, while the single-family impact is just south of Main Street.

With Alternative C7E no vibration or groundborne noise impacts are predicted. Alternative C8E would have vibration mitigation along the elevated guideway just north of Main Street for a hotel and multifamily residence, and again along 108th Avenue NE for two additional multifamily units. There would also be vibration mitigation north of NE 12th Street to mitigate two single-family residences with vibration impacts. Alternative C9A would require vibration mitigation for two single-family residences south of Main Street, three multifamily residences along 110th Avenue NE, and at the Coast Bellevue Hotel. Alternative C14E would also require vibration mitigation along the elevated guideway for impacts predicted at three hotels.

There would be no vibration or groundborne noise impacts in Segment D, and no vibration mitigation is recommended.

With *Preferred Alternative E2* and the E2 – Redmond Transit Center Design Option, an estimated 700 feet of vibration mitigation would be required along SR 520 to mitigate vibration impacts on three single-family residences. Vibration impacts and mitigation would be the same under Alternative E1 as described for *Preferred Alternative E2*. With Alternative E4, vibration mitigation would be required at one single-family residence along SR 520, a group of multifamily units off Leary Way, and the Residence Inn Hotel.

4.7.5.4 Construction Vibration Mitigation Measures

In general, building damage from construction vibration would only be anticipated from impact pile driving close to buildings. If piling is more than 50 to 100 feet from buildings, or if alternative methods, such as auger cast piling or drilled shafts are used, then damage from construction would not be anticipated. Other sources of construction vibration, including potential ground improvement activities in Segment B such as construction of subsurface stone columns, could generate high enough vibration levels for localized damage to occur, depending on the soil type and distance between the source of vibration and the nearest building. In any locations of concern, preconstruction surveys would be conducted to document the existing condition of buildings, in case there was an issue during or after construction, and vibration monitoring would be implemented during construction to establish levels of vibration. Where levels of vibration exceed preset limits for damage, the contractor would be required to stop work and switch to alternate construction methods.

Measures to minimize short-term annoyance from groundborne vibration and groundborne noise from construction activities such as pile installation or compaction of earth fills include use of alternate methods that result in less vibration or noise, such as auger cast piles or drilled shafts in place of driven piles, or use of static roller compactors rather than vibratory compactors. The hours and duration of these types of activities can also be restricted to hours when vibrations and noise are less noticeable. Vibration monitoring would be considered for pile driving, tunnel construction, vibratory sheet installation, and other construction activities that have the potential to cause high levels of vibration.

Sound Transit would minimize vibration at the Winters House during construction and prevent damage or limit to minor cosmetic damage by using the following methods:

- Install monitoring equipment and monitor vibration during construction.
- Place limits on the construction vibration levels for the contractor, with the contractor selecting one or more of the following measures or other measures of equivalent effectiveness to limit construction:
  - Using auger-drilling methods
  - Using low vibration or nonimpact methods of installing steel casing required to support construction of drilled shaft or secant pile foundations
  - Using slurry confinement (i.e., temporarily filling the cavity with slurry material to replace the removed soil)
  - Underpinning foundation and employing structural support or soil stabilization if needed
  - Adjusting excavation methods based on monitoring results
  - Installing a shallow temporary supporting wall
  - Monitoring vibration levels associated with equipment to be used for the East Link Project at other construction sites with similar soils before project construction to determine which vibration-minimization method would be necessary
  - Beginning vibration-inducing construction at the site at points more distant from the Winters House to enable the contractor to determine which vibration-minimization method would be necessary
  - Photograph and inventory the building to establish existing conditions to determine if any damage is caused by construction, and repair the building in a manner consistent with the U.S. Department of the Interior Secretary's standards for treating historic properties.

4.8 Ecosystem Resources

4.8.1 Introduction and Regulatory Requirements

An ecosystem is a system formed by the interaction of a community of organisms with its environment (Webster's College Dictionary, 1991). Ecosystems are composed of living organisms, including humans, and the environment they inhabit. Understanding this relationship is basic to the environmental review process and the assessment of impacts on ecosystems. Sound Transit identified vegetation, wetlands, and aquatic habitat in the study area that would support fish and wildlife.

High-value wildlife habitat generally is made up of moderately to mostly vegetated areas consisting of shrubs, forest, and other habitat known to support sensitive wildlife species. Wetland quality was determined using the Washington State Department of Ecology's (Ecology's) *Washington State Wetland Rating System for Western Washington* (Hruby, 2004). High-quality aquatic habitat was identified based on the quality of the riparian habitat and in-stream habitat.

Components of ecosystems are protected by federal, state, and local regulations. Such regulations govern the planning, land use, and management activities that have the potential to affect and influence fish and wildlife species and their habitats within the project vicinity. Key regulations include the following:

- Sections 404, 402, and 401 of the Clean Water Act (CWA)
- Migratory Bird Treaty Act (MBTA)
- International Migratory Bird Treaty Act
- Endangered Species Act (ESA)
- Magnuson-Stevens Fishery Conservation and Management Act (MSA)
- Bald and Golden Eagle Protection Act (Eagle Act)
- Washington State Hydraulic codes
- Washington State Water Pollution Control Act
- Critical Area Ordinances for the Cities of Bellevue, Mercer Island, Redmond, and Seattle
- Washington Department of Fish and Wildlife (WDFW) Priority Habitats and Species (PHS) Management Recommendations
- Coastal Zone Management Act
- Shoreline Management Act (SMA)/local agency Shoreline Master Programs (SMPs)

Sound Transit has prepared the Ecosystems Technical Report (Appendix H3), which covers federal and state threatened, endangered, and species of concern; wildlife and vegetation; wetlands; and aquatic resources. Sound Transit has also prepared a Biological Assessment to meet ESA requirements. This section summarizes the findings in Appendix H3 and is based on literature research, communication with regulatory agencies, field assessment of resources (where property access was allowed), and preliminary field reconnaissance of resources (where property access was not allowed). Habitat types were studied within the following boundaries:

- **Vegetation**. The area within 100 feet of either side of the project alternatives. Vegetation areas were classified and mapped regardless of size or upland/ wetland designation. As a result, the vegetation areas may include upland and/or wetland vegetation, and, therefore, may overlap with wetland areas. This overlap is depicted on Exhibits 4.8-1 through 4.8-4.
- **Wetlands and wetland buffers.** The area within 200 feet of either side of the project alternatives.
- **Aquatic habitat.** A distance extending 100 feet upstream to 300 feet downstream from where project limits cross the stream, and the entire stretch of any stream paralleling the project within 200 feet of the edge of the alternative.

Appendix H3 contains additional detail on methodology, affected environment, impacts, and potential mitigation measures.

4.8.2 Affected Environment

The ecosystem evaluation was based on literature reviews; consultation with federal, state, and local agencies and their websites; field work; and aerial mapping. Habitats in the project vicinity have been modified considerably from predevelopment conditions before the arrival of EuroAmerican settlers to the region. Wildlife species present in these modified habitats have adapted to smaller habitat patches and tolerate moderate to high human activity. Areas with lower levels of human activity and larger patches of relatively undisturbed habitat generally support the largest number and highest diversity of wildlife species in the project vicinity.

The areas in the project vicinity that have the largest habitat patches and that support the most wildlife are Lake Washington; Mercer Slough Nature Park; aquatic and terrestrial habitats associated with streams described in Section 4.8.2.3; and larger patches of deciduous, coniferous, and mixed forests that occur along Segments B, D, and E. A number of these forested areas border the study area and extend for several hundred feet parallel and perpendicular to the alternatives.

Exhibit 4.8-4 **Vegetation/High-Value Wildlife Habitat, Aquatic Habitat, and Wetlands, Segment E**
East Link Project

The following subsections describe the habitat types that are found in the study area and discuss these habitat types by project segment. These habitat types were assessed by applying classification systems specific to the habitat type and as they relate to the likely presence of one or more threatened and/or endangered species or species protected by local critical areas ordinances. This section describes habitats in terms of vegetation types, wetlands, and aquatic resources.

4.8.2.1 Vegetation/High-Value Habitat

Non-aquatic ecosystems typically are defined by vegetation types. The study area crosses through highly urbanized environments with some key pockets of natural vegetation and water bodies. Pockets of vegetation and habitat types in the study area were classified following a system that was used for Sound Transit's Central Link Project. This system was modified from the King County (1987) Wildlife Habitat Profile (Sound Transit, 1999) and categorizes vegetation in terms of high, moderate, and low value as wildlife habitat.

Vegetation types in the study area were characterized as shown in Exhibits 4.8-1 through 4.8-4. These vegetation types are also designated by WDFW as priority habitats and are known to support federal and state threatened and endangered species. Segment A is not included in the exhibits because Lake Washington is the only high-value habitat in that segment.

Habitat Value

Terrestrial plant communities, wetlands, and aquatic systems such as streams provide a variety of functions in the environment. The value of these functions is determined by the habitat's ability to support the needs of biological species. High-value habitats are those that support or may support threatened, endangered, and/or sensitive species as determined by the federal, state, and local jurisdictions. For instance, wetlands generally offer high habitat value because they provide many functions, such as water quality improvement, groundwater recharge, nutrient and sediment filtering, habitat for a variety of animals, and education and recreation opportunities for people.

Low- and moderate-value habitat types are not shown because the habitats are either too narrow to sustain wildlife species or the vegetation types do not readily support federal or state priority species.

The following urban vegetation types with **high-value habitat** are found in the study area:

- Wetlands (wetlands are defined below)
- Coniferous forests, typically containing Douglas–fir, hemlock, and red cedar
- Deciduous forests, including big-leaf maple, black cottonwood, and red alder
- Mixed coniferous and deciduous forests
- Riparian forest, including big-leaf maple, black cottonwood, red alder, and willow, located adjacent to water bodies

These high-value habitats and/or the species they support are often regulated by local Critical Areas Ordinances and state and federal laws and regulations.

4.8.2.2 Wetlands and Wetland Buffers

Seventeen wetlands were identified in the study area. Wetlands are shown in Exhibits 4.8-1 through 4.8-4 and described in Table 4.8-1. There are no wetlands within the defined Segment A study area. In general, wetlands in the study area have been altered and are surrounded by urban and residential environments.

Wetlands are defined by soil characteristics, the presence or absence of hydrology, and dominance of vegetation adapted to wet environments. Many wetlands and aquatic habitats in the study area are considered jurisdictional waters, including wetlands of the United States by the U.S. Army Corps of Engineers (USACE), and are protected under the CWA Section 404. These wetlands require a permit from the USACE for any discharge of dredged or fill material into waters of the United States.

Generally, wetlands provide wildlife habitat, but they can be further classified in terms of the level of wildlife/biological habitat, hydrologic, and water quality function they provide. Sound Transit categorized and classified wetlands using Ecology's *Washington State Wetland Rating System for Western Washington* (Hruby, 2004). Local jurisdictions in the study area have adopted Ecology's rating system without modification. Wetland buffers, as defined by the state or specific local jurisdiction regulating the wetland, were also identified.

Various levels of wetland functions have been identified in the study area. The wetland rating system (Hruby, 2004) defines three main wetland functional categories: water quality, hydrologic, and habitat. The degree to which several functions are performed by a wetland (e.g., enhancing water quality, reducing floods, and providing fish and wildlife habitat) result in a higher category assignment, with Category 1 (I) offering the highest function and Category 4 (IV) offering the lowest. The assessments used for these ratings can be found Appendix H3.

TABLE 4.8-1

[a] Category is based on Ecology's rating system (Hruby, 2004), which the Cities of Bellevue and Redmond adopted without modification.

4.8.2.3 Aquatic Habitat

One lake and 10 streams were identified in the study area. Lake Washington is the second largest natural lake in the state and the largest lake in King County. It is fed by the Sammamish River at its north end and the Cedar River at its south. Lakes are most often classified based on their productivity: the amount of algae and aquatic plants that the lake can support. They also may be classified based on size or hydrology (drainage), plant or animal communities, or the way humans use them (water supply, recreation, amount of development, and navigation). Lake Washington is classified as oligotrophic (low biological productivity) (King County, 2010). Streams in the study area (defined as a body of water with a current, confined within a bed and stream banks) were classified based on existing conditions using King County, Washington Department of Natural Resources (WDNR), City of Bellevue, and City of Redmond classification systems. The classification systems are described in more detail in Appendix H3. Each of these classification systems are based on channel width, flow rate, flow regime, and presence or absence of salmonids. Each system is very similar to the others but has different category names.

Table 4.8-2 identifies and describes water bodies located in the study area and lists those most likely to support salmonids (salmon and trout). There is no nontribal commercial fishing in the aquatic study area. Sound Transit consulted with the Muckleshoot Tribe about Usual and Accustomed Treaty Rights that provide the tribe with unique fishing, hunting, and gathering rights. The Tribe expressed concern about impacts of the project on their fishery on Lake Washington, the Lake Washington Ship Canal, and outside of the Hiram Chittenden (Ballard) Locks. In the recent past, this fishery has been used for sockeye salmon (Oncorhynchus nerka). In the future, however, other fisheries might be opened by the Pacific Fishery Management Council in association with the Western Washington Treaty Tribes.

TABLE 4.8-2
Water Bodies, Aquatic Habitat Quality, and Aquatic Species in the Study Area

Water Body	Aquatic Habitat Quality	Aquatic Species Present	Comments
Segment A, Interstate 90			
Lake Washington	Good, although there are recorded longer, warmer stratification periods linked to declines of key organisms in the food chain that salmonids depend on. Some areas of spawning habitat for sockeye salmon.	Chinook, steelhead, sockeye, coho, bull trout, rainbow and cutthroat trout, smallmouth bass, yellow perch, peamouth, river lamprey, and western toad.	A regionally important lake and designated as a shoreline of statewide significance. An important migratory corridor for Chinook.
Segment B, South Bellevue			
Mercer Slough	Poor; lack of riffles and gravel and high summer temperature. No spawning habitat for salmonids.	Chinook, sockeye, steelhead, and coho pass through to spawn in Kelsey Creek; smallmouth bass.	Chinook gather in the mouth of Mercer Slough under I-90 crossing. All salmonids destined for Kelsey Creek pass through Mercer Slough.
Kelsey Creek	Poor spawning and rearing habitat. Habitat has been degraded by clearing and urban development.	Chinook, sockeye, coho, steelhead, and sea-run cutthroat; peamouth spawning.	Largest stream in Bellevue. This is an urban stream of regional significance due to high presence of Chinook. Urbanized area results in a rapidly fluctuating flow regime. An important migratory corridor for Chinook.
Sturtevant Creek	Poor spawning and rearing habitat. Habitat has been degraded by logging and urban development. All tributary inflows are through piped systems.	Chinook and sockeye up to the impassable culvert at I-405; peamouth spawning.	Urbanized area results in a rapidly fluctuating flow regime.
Segment C, Downtown Bellevue			
Sturtevant Creek	Fair to good spawning and rearing habitat.	Chinook and sockeye up to impassable culvert at I-405. Peamouth spawning.	Urbanized area results in a rapidly fluctuating flow regime.
Segment D, Bel-Red/Overlake			
West Tributary to Kelsey Creek	Poor spawning but good rearing habitat. Habitat has been degraded by urban development.	Chinook, sockeye, coho, steelhead and cutthroat below Bel-Red Road.	Pacific giant salamander documented. Impassable culvert at Bel-Red Road.
Goff Creek	Fair to poor spawning and rearing habitat depending on reach.	Chinook and sockeye salmon below Bel-Red Road; cutthroat trout.	Urbanized area results in a rapidly fluctuating flow regime. Impassable culvert at Bel-Red Road.
Unnamed tributary to Kelsey Creek	Poor spawning and rearing habitat. Very small	None known to use this tributary.	Very small, ditch-like at crossing. Urbanized area and low intermittent flow regime.
Valley Creek	Poor to good spawning and rearing habitat depending on reach.	Sockeye (historically), Chinook, steelhead, coho, and cutthroat trout.	Urbanized area results in a rapidly fluctuating flow regime.
Sears Creek	Fair spawning and rearing habitat because of some presence of pools and clean gravel riffles.	Known use by Chinook, coho, and cutthroat trout up to the NE 20th Street culvert.	Urbanized area results in a rapidly fluctuating flow regime. Most of drainage is piped.
Segment E, Downtown Redmond			
Sammamish River	Highly degraded with very little spawning and poor rearing habitat, limited riparian vegetation, high summer temperatures.	Migratory corridor use by Chinook, coho, and kokanee (resident sockeye); steelhead; cutthroat trout.	No spawning. On the State 303(d) list for high temperatures. Sammamish River provides a critical migratory corridor for salmon returning to Bear Creek.
Bear Creek	Overall good spawning and rearing habitat quality.	Chinook, coho, sockeye, and kokanee salmon; steelhead; and cutthroat trout. All spawn in Bear Creek.	Identified as one of the top six natural resource basins in King County. There is a major watershed planning effort for this watershed. Classified as a shoreline of statewide significance. An important migratory corridor for Chinook.

4.8.2.4 Threatened and Endangered Fish and Wildlife Species, Species of Concern, and WDFW Priority Species

Sound Transit searched the WDFW's PHS database (2010) for priority species within one-half mile from the outermost routes, which is the widest impact analysis area required for any listed species. No priority plant species were found within the study area. The only federal or state threatened or endangered species known to exist in the study area are Puget Sound Chinook salmon (Oncorhynchus *tshawytscha*), coastal-Puget Sound bull trout (*Salvelinus confluentus*), and Puget Sound steelhead *(Oncorhynchus mykiss*). During the nonbreeding season, marbled murrelets (*Brachyramphus marmoratus*) are rare visitors to Lake Washington. They have been observed on the lake in the past but have only been documented once in the past 50 years. Additionally, WDNR requires the submittal of a Bald Eagle Management Plan (WAC 232-12-292) if a bald eagle (*Haliaeetus leucocephalus*) nest is found within one-half mile of the construction limits.

Table 4.8-3 lists all federal endangered, threatened, and candidate species and state endangered, threatened, and sensitive species likely to occur in the study area. This assessment includes research of the existing habitat types that would support these species and investigates known species-sighting locations.

In addition to the listings in Table 4.8-3, a large number of state-monitored species also occur within the project vicinity. WDNR monitors other species for which there is no current protection mandated. Particularly in wetlands and water bodies, many of these species are known to occur within the project vicinity, including the following birds: osprey (Pandion haliaetus), red-necked grebe (Podiceps grisegena), horned grebe (Podiceps auritus), great blue heron (Ardea herodias), great egret (Ardea alba), turkey vulture (Cathartes aura), and black tern (Chlidonias niger), black swift (Cypseloides niger), and Vaux's swift (Chaetura vauxi). Also, the Monarch butterfly (Danaus plexippus), Dreamy duskywing (Erynnis icelus), and Townsend's big-eared bat (Corynorhinus townsendii) are state-monitored species that are likely present within the study area.

In addition to federal and state species of concern, the local jurisdictions' Critical Areas Ordinances were considered. The following summarizes applicable ordinances within the study area:

- **Section 198 of the King County Comprehensive Plan** requires the county to protect the active breeding sites of these species, as well as the immediate area surrounding each site to prevent any disturbance to breeding activities. The species include the bald eagle, great blue heron, osprey, peregrine falcon (*Falco peregrinus*), northern spotted owl (*Strix occidentalis*), marbled murrelet, Townsend's big-eared bat, Vaux's swift, red-tailed hawk (*Buteo jamaicensis)*, and goshawk (*Accipiter gentilis*).
- The **City of Mercer Island Comprehensive Land Use Plan** includes Ordinance No. 05C-12, which details its critical areas regulations. To streamline its critical areas regulations, the City of Mercer Island adopted WDFW's Priority Habitat and Species program in its entirety in 1998.
- **Bellevue's Land Use Code 20.25H.025** requires any habitat associated with a species of local importance to be designated a critical area. Furthermore, if a habitat associated with a species of local importance is impacted by a proposed development, the proposal shall implement the WDFW wildlife management recommendations designed for that species. If the habitat does not include a critical area or critical area buffer but is occupied by a locally important species, then only the guidelines in the wildlife management recommendations need to be followed. Species of local importance in Bellevue are numerous and are listed in Table 4.8-3.
- The **City of Redmond's Critical Areas Ordinance** (Ordinance No. 2259) applies species protection to State Species of Concern, Priority Species designated by WDFW, and locally important species. The only locally important species is the great blue heron.

4.8.2.5 High-Value Habitats, Wetlands, and Aquatic Habitats Supporting Species of Concern

This subsection provides a general description of wetland, aquatic, and high-value upland habitats that support the species listed in Table 4.8-3 for each segment. Also, to the extent available, it provides information on species-of-concern sightings that was obtained through data research, interviews with regulatory representatives, and field surveys. The following descriptions do not include ESA protocol surveys and, therefore, do not provide a complete reconnaissance of present species of concern. For the following federally listed species (marbled murrelet, Chinook salmon, steelhead, and bull trout), critical habitat is noted if designated as such in Table 4.8-3.

TABLE 4.8-3
Federal and State Species of Concern, Including Threatened and Endangered, Found in Western Washington; Locally Important Wildlife; and Potential Occurrence in East Link Study Area

Name	Federal/State Status [a]	Bellevue Species of Local Importance	Presence, Preferred Habitat, and Probable Location in Study Area
Birds			
Bald eagle (*Haliaeetus leucocephalus*)	Federal species of concern and state monitored	Yes	**Known in the study area.** Closely associated with lakes and large rivers with mature trees. Nest near open water in late successional (i.e., mature) forest and occur in areas with low to relatively high levels of human disturbance. Wintering populations are found throughout the Puget Sound region. Bald eagles are sighted in Segments A, B, C, and E.
Marbled murrelet (*Brachyramphus marmoratus*)	Federal and state threatened	No	**Extremely rare in the study area**. Requires conifer forests with trees more than 28 inches in diameter at breast high with platforms for nesting. Spends the winter in marine waters offshore. Rare and infrequent visitors to Lake Washington during the nonbreeding season. Only observed once in the last 50 years on Lake Washington. Only potentially in Segment A. Critical Habitat: None present in the study area.
Peregrine falcon (*Falco peregrinus*)	Federal species of concern and state monitored	Yes	**Likely present in the study area.** Far-ranging flier that nests and roosts on cliffs and, in cities, on bridges and ledges of tall buildings. In winter, peregrine falcons can be found in the southwestern portion of Puget Sound and lowlands in western Washington. Sightings and potential viable habitat in Segments A, B, C, and E.
Pileated woodpecker (*Dryocopus pileatus*)	State candidate	Yes	**Known in the study area.** Typically found in forests with a component of dead and dying trees and snags for foraging and nesting. Found at Marymoor Park and throughout the study area. One bird observed near I-405 south of SE 8th Street. Likely habitat along BNSF Alternative (B7) and *Preferred Marymoor Alternative (E2)* due to larger clusters of larger trees and snags.
Purple martin (*Progne subis*)	State candidate	Yes	**Known in the study area.** Nests in structures over water bodies, including natural cavities, pilings, and manmade housing structures. Forages over open water or wet areas for insects while in flight. Nesting observed at Marymoor Park in 2003 (*Preferred Alternative E2*), but no activity since. Habitat may also be present in Segment B as well.
Western grebe (*Aechmophorus occidentalis*)	State candidate	Yes	**Known in the study area.** Nests in colonies numbering up to several hundred birds east of the Cascade Mountain range and is a winter resident on Lake Washington and Puget Sound. The highest likelihood of occurrence is in Segment A.
Merlin (*Falco columbarius*)	State candidate	Yes	**Likely present in the study area.** Seen during the nesting season at Marymoor Park. Commonly found throughout western Washington, including urban areas, in winter and during migration. May occur in Segments A, B, D, and E.
Olive-sided flycatcher (*Contopus borealis*)	Federal species of concern	No	**Likely present in the study area.** Breeds in coniferous forests in North America. Common in most forest openings throughout Washington and sometimes found in city parks or suburban areas, especially during migration. Potential habitat in Segments B and E.
Willow flycatcher (*Empidonax traillii*)	Federal species of concern	No	**Known in the study area.** Breeds in deciduous thickets, especially in willow thickets. Nest sites are often close to water. Present in Segments B and E.
Great blue heron (*Ardea herodias*)	-	Yes	**Known in the study area.** Nests in small- to medium-sized colonies ranging from 3 to 30 nests. Colonies usually in secluded deciduous forests but can adapt to some levels of disturbance gradually over time. Will use conifer forests occasionally. Colonies often less than 1 mile away from wetland or large water bodies. Listed due to its sensitivity to disturbances and dependence on wetlands, wet meadows, and water bodies.
Red-tailed hawk (*Buteo jamaicensis*)	-	Yes	**Known in the study area.** Found in areas with a mix of forests and open spaces, including agricultural land, grasslands, wetlands, and meadows. Small mammals, especially rodents, are their primary prey.
Osprey (*Pandion haliaetus*)	-	Yes	**Known in the study area.** Nests in exposed trees or platforms that provide a clear, unobstructed view of surrounding area. Nests close to large bodies of water. Territorial. Several known active nests and territories in Segments B, C, and E.
Common loon (*Gavia immer*)	-	Yes	**Known in the study area**. Population has declined due to acid rain, pollution, industrial contamination of water bodies, and lead poisoning. Artificial floating nesting platforms have reduced the negative impact of fluctuating water levels from human activities to nests.
Green heron (*Butorides virescens*)	-	Yes	**Known in the study area**. Breeds in small wetlands on a platform-built nest that is either in a tree or shrub, close to the water. Feeds on small fish, insects, and amphibians. Nests at Marymoor Park.
Vaux's Swift (*Chaetura vauxi*)	-	Yes	**Known in the study area**. Nests and forages in groups with 30 or more birds. Nest is a cup-shaped nest placed in a dark, confined cavity. Breeds in mountains and foothills, usually more than 700 meters in elevation. Forages over wooded areas and more open habitats, including towns.

TABLE 4.8-3 CONTINUED
Federal and State Species of Concern, Including Threatened and Endangered, Found in Western Washington; Locally Important Wildlife; and Potential Occurrence in East Link Study Area

Name	Federal/State Status [a]	Bellevue Species of Local Importance	Presence, Preferred Habitat, and Probable Location in Study Area
Mammals			
Townsend's big-eared bat (*Corynorhinus townsendii*)	-	Yes	**May occur in the study area.** Areas with a mosaic of woodland/grassland and/or shrub land, especially coniferous mosaics. Found in Pierce County, Fort Lewis.
Keen's myotis (*Myotis keenii*)	-	Yes	**Unlikely to occur in the study area.** Keen's myotis has one of the most limited ranges of any bat species in North America**.** Habitat use is restricted to dense forests with old growth characteristics. Range is limited to the Olympia Peninsula and low elevation conifer forests in Puget Sound region.
Long-legged myotis (*Myotis volans*)	-	Yes	**May occur in the study area.** Occurs in forested areas statewide. Prefers mountainous, coniferous forests. Often found along forest edges, can occur at high elevations in cool, wet forests.
Long-eared myotis (*Myotis evotis*)	-	Yes	**May occur in study area.** Found in wooded areas statewide; however, it is most common in eastern Washington lodgepole pine forests. Does occur in humid coastal forests with good ground cover. Will occur in any forested habitat except those with no ground cover or in mid-to-high density developments.
Amphibian and Reptile			
Western toad (*Bufo boreas*)	Federal species of concern/ state candidate	Yes	**Known in the study area.** Found in Lake Washington (Segment A) and possibly other water bodies in the study area. May also be present in Segments B, D, and E.
Oregon spotted frog (*Rana pretiosa*)	-	Yes	**Unlikely to occur in the study area.** Highly aquatic amphibian, usually found in or near permanent bodies of still water 9 acres in size or more, including lakes, marshes, and wetlands, and vegetated, slow-flowing perennial streams. Population has experienced heavy declines in the last 20 years. In 1997, only three known populations remained in Washington.
Western pond turtle (*Clemmys marmorata*)	-	Yes	**Unlikely to occur in the study area.** The western pond turtle is a highly aquatic turtle that has been extirpated from almost all of its Washington range. The Washington population consists of a few isolated and scattered populations. The range historically included streams, ponds, lakes, and permanent and ephemeral wetlands throughout the Puget Sound lowlands.
Fish			
Puget Sound Chinook salmon (*Oncorhynchus tshawytscha*)	Federal threatened/ state candidate	Yes	**Known in the study area.** Found in Lake Washington, Sammamish River, and Bear Creek, Mercer Slough, Kelsey Creek, West Tributary to Kelsey Creek, Goff Creek, Valley Creek, and Sears Creek. Found in Segments A, B, D, and E. Critical Habitat: Present in all of the waters listed above.
Puget Sound-Strait of Georgia coho salmon (*Oncorhynchus kisutch*)	Federal species of concern	Yes	**Known in the study area.** Found in Lake Washington, Sammamish River, and Bear Creek, Mercer Slough, Kelsey Creek, West Tributary to Kelsey Creek, Goff Creek, Valley Creek, and Sears Creek. Found in Segments A, B, D, and E.
Puget Sound Steelhead trout *(Oncorhynchus mykiss*)	Federal threatened	No	**Known in the study area.** Found in Lake Washington. Presumed to be present in Mercer Slough, Kelsey Creek and its tributaries, Sammamish River, and Bear Creek. Possibly present in Sturtevant Creek. Found in Segments A, B, D, and E. Critical Habitat: Not designated at this time.
Coastal-Puget Sound bull trout (*Salvelinus confluentus*)	Federal threatened/ state candidate	Yes	**Known in the study area**. Found in Lake Washington, and possibly in Sammamish River and Bear Creek, but rare in all cases. Found in Segment A, and possibly in Segment E. Critical Habitat: Limited to only Lake Washington within the study area.
River lamprey (*Lampetra fluviatilis*)	Federal species of concern/ state candidate	Yes	**Known in the study area.** Found in Mercer Slough, Kelsey Creek, Sammamish River, and Bear Creek. Found in Segments A, B, and E.

[a] Washington species of concern include only native Washington fish and wildlife species that are listed as endangered, threatened, or sensitive, or as candidates for these designations as established in the Washington Administrative Code.

Source: (Csuti et al., 2001; Friends of Marymoor Park, 2009; Kaufman and Brock, 2003; Opler and Wright, 1999; Seattle Audubon Society, 2009; Sibley, 2000; Stebbins, 2003; UWFWS, 2009; WDFW, 2009; Wahl et al., 2005)

Segment A

Lake Washington is an important water body for aquatic and avian species. Bald eagles, osprey, peregrine falcons, and great blue heron use the lake as foraging grounds. WDFW recorded that three peregrine falcon nests are located within one-half mile of the study area. One is located under the I-90 floating bridge across Lake Washington just above the Seattle shoreline, and the second one is located under the East Channel bridge on the Mercer Island side. During a field visit in March 2007, project biologists were unable to locate either of the nests. The Washington State Department of Transportation (WSDOT) indicates there has not been a recorded successful nest under the I-90 floating bridge for the past 2 years. The nest under the East Channel bridge has been successful for the past 3 to 4 years, and is expected to remain successful as long as the adults live. A third nest is located in Downtown Bellevue (WDFW PHS database, 2010). There are no communal bald eagle roosts, winter concentration areas, or buffers for such areas within one-half mile of any of the proposed project components in Segment A. However, five active eagle territories are located within one-half mile of *Preferred Interstate 90 Alternative (A1)*. Of these, three nests were known to be active, with incubating adults roosting outside the study area in April 2007. Chinook, sockeye, and coho salmon *(Oncorhynchus kisutch)*, steelhead, cutthroat, and bull trout are known to occur in Lake Washington. Table 4.8-4 shows their residence period in the lake and in the particular streams in the study area where these species are known to spawn.

TABLE 4.8-4
Anadromous Salmonids in Lake Washington

Species	Time Period in Lake Washington	Spawning Streams
Summer and fall Chinook salmon	Adults, June to mid-December; smolts, March to July	Cedar River, North Creek, May Creek, Little Bear Creek, Swamp Creek, Kelsey Creek and tributaries, Bear Creek, Issaquah Creek. All are part of designated critical habitat.
Steelhead trout	Adults, December through April; smolts, April and May	Tributary streams and rivers including Bear Creek. Critical habitat not designated.
Bull trout	A few fish documented in the lake each year	Unknown if bull trout spawn in the Lake Washington system. Designated critical habitat limited to Lake Washington only.
Coho salmon	Adults, August to February; smolts, March through June	Too many to list. Most tributaries except the smallest. Issaquah Hatchery
Sockeye salmon	Adults, April to mid-December; fry, juveniles, and smolts, all year	Cedar River, Kelsey Creek and tributaries, North Creek, Little Bear Creek, Bear Creek, and Issaquah Creek
Sea-run cutthroat trout	Adults, April and May; smolts, March through July	Too many to list. Most tributaries except the smallest

Segment B

High-value wildlife habitats (as described in Section 4.8.2.1) are associated with Mercer Slough in Segment B. Mercer Slough serves as a migratory corridor for anadromous salmonids from Lake Washington to reach several streams (Kelsey and Sturtevant Creeks). Mercer Slough Nature Park is the largest freshwater wetland remaining along the shores of Lake Washington. Although not identified during field survey efforts, additional wetlands may be present in the Bellefield Office Park. Several existing wetland mitigation sites are located in the Mercer Slough (see Exhibit 4.8-1). The park encompasses 320 acres and is composed of herbaceous, scrub-shrub, and forested wetland; upland forest; meadows; and a blueberry farm. However, noxious and invasive weeds (such as Japanese knotweed, purple loosestrife, reed canarygrass, and Himalayan blackberry) are invading the wetlands and/or buffers. Red-tailed hawks (*Buteo jamaicensis*) are regularly seen and known to nest in the Mercer Slough Nature Park.

The City of Bellevue indicated that there was a historic heron rookery in Mercer Slough Nature Park, but the rookery is no longer active. However, great blue heron are sighted in the Mercer Slough vicinity (City of Bellevue, 2008).

North of Mercer Slough Nature Park is the Sturtevant Creek Wetland, through which Sturtevant Creek flows. Signs of recent beaver activity have been observed. Habitat is limited by the surrounding roads, office buildings, parking lots, and a new hotel. Noxious and invasive weeds (such as reed canarygrass and Himalayan blackberry) are invading this wetland and its buffers.

Segment C

There is minimal wildlife habitat available in Segment C; however, an osprey nest is located less than one-half mile west of Downtown Bellevue. Lake Bellevue is located east of the former BNSF Railway corridor just east of Overlake Hospital. This lake offers minimal habitat value because the only fish known to exist in the lake are goldfish, vegetation is sparse, the bottom is silt and organic material, and dense development surrounds the lake. Sturtevant Creek leaves Lake Bellevue as a featureless glide in the ditch alongside the tracks in the former BNSF Railway corridor. Riparian vegetation is sparse and mostly grasses or blackberries but also includes some cottonwood and willow trees near Lake Bellevue. The channel substrate composition consists of sand and silt, and habitat quality is poor. Sturtevant Creek is in a pipe system for much of the reach between NE 8th Street and the I-405 crossing. The stream is blocked to fish passage at the I-405 culvert next to the Hilton Hotel.

While most of Sturtevant Creek has minimal habitat value, the short reach adjacent to the Hilton Hotel (shown on Exhibits 4.8-1 and 4.8-2 as Hilton Stormwater Pond), north of the SE 6th Street crossing, has good in-stream habitat because there are pools and riffles with moderately clean gravel; this is virtually the only usable spawning habitat in Sturtevant Creek for salmonids.

Segment D

There are nine wetlands with varying habitat value in this segment. High-value habitats, including a riparian wetland, are located along the West Tributary to Kelsey Creek, along State Route (SR) 520 (some vegetated strips), and along portions of Valley Creek. Lower reaches of Goff Creek and the West Tributary to Kelsey Creek support salmonid spawning, while culverts in the middle reaches block fish passage. Valley Creek has some good in-stream habitat because there are some riffles with a few pools and mature riparian vegetation. Although Sears Creek is confined and there is a lack of riparian vegetation, it provides fair habitat because there are pools and riffles, and there is considerable use of the creek by salmon up to where it is blocked by the culvert under NE 20th Street.

The City of Bellevue plans to enhance Goff Creek and West Tributary to Kelsey Creek as part of implementation of the Bel-Red Corridor Project in Segment D. Funding for early implementation of the Bel-Red Corridor Project is included in the City's 2007-2013 Capital Improvement Program.

The Unnamed Tributary to Kelsey Creek has a very low base flow and is sometimes intermittent. The entire drainage lies within a commercial district and is piped or in a roadside ditch for much of its length. There are no habitat features such as pools or riffles in the potentially affected reach. Gradient is flat, and substrates consist of grass, silt, and sand. The channel has a category 4 wetland fringe in this reach, but it does not add habitat value because it consists of mowed grasses. The entire creek is above a fish passage block and there is no spawning habitat; therefore, it is highly unlikely that salmonids are present.

Segment E

In Segment E, there is limited high-value habitat along the Sammamish River, which is used by a variety of waterfowl and salmon. The 640-acre Marymoor Park has a variety of habitats, including herbaceous, scrub-shrub, and forested wetlands; a riparian corridor; deciduous upland forest; and grassy fields. There is a constructed wetland mitigation site near the northern boundary of the park. There are several permanent or semi-permanent priority species nests in Marymoor Park. Two bald eagle nests, an osprey nest, and a red-tailed hawk nest are located within the park boundaries. The osprey nest is located on an artificial platform within 0.1 mile of SR 520, while the other nests are over one-half mile from the study area. Several nest boxes are set up for purple martins (*Progne subis*) at the south end of the park, and they have used these nest boxes in the past. However, since 2008, usage of these boxes by purple martins is uncertain (Hobbs, 2011). Also, a reported heron rookery near Leary Way has been abandoned.

The Bear Creek basin drains about 50 square miles of suburban and rural land. Bear Creek basin remains one of the more productive stream systems in the region. The diversity and number of aquatic resources in the Bear Creek basin distinguish it as one of the top six natural resource basins in King County in the Waterways 2000 Program (Kerwin, 2001). Bear Creek offers some high-value riparian and in-stream pool habitat near the east portion of the Town Center Open Space. Farther to the west, nonnative vegetation has been removed and replanted with native shrubs and tree saplings as part of a habitat restoration project. The City of Redmond has plans to rehabilitate the lower 3,000 feet of Bear Creek to improve fish habitat.

Maintenance Facility Surroundings

Two small areas of urban, mostly vegetated, deciduous forest are located south of the 116th (MF1) and BNSF (MF2) maintenance facilities. The SR 520 Maintenance Facility (MF3) is surrounded by small office parks and retail stores. The SE Redmond Maintenance Facility (MF5) is surrounded by commercial and light industrial development.

4.8.3 Environmental Impacts

There are two types of impacts discussed in this section: permanent operational impacts within the permanent project right-of-way and temporary construction impacts between the permanent project right-of-way and the construction areas.

For analysis of the East Link Project environmental impacts, it was assumed that Sound Transit would already have implemented a series of avoidance and best management practices (BMPs) during construction. These practices are described in Appendix H3. In short, these include but are not limited to:

- Designating construction zone limits
- Implementing a Temporary Erosion and Sediment Control (TESC) plan
- Implementing the terms and conditions in the Hydraulic Project Approval (HPA) for any work within or below the ordinary high water mark
- Following the requirements of the National Pollution Discharge Elimination System (NPDES) permit program
- Treating and monitoring weeds consistent with the King County Noxious Weed Control Board direction
- Implementing Ecology requirements for permanent stormwater runoff, flow controls, and pest management in accordance with current agreements

For analysis of temporary construction impacts on ecosystem resources, Sound Transit assumed that all uplands and wetlands within the construction and staging areas would be disturbed during construction and that all vegetation would be removed. Short-term temporary turbidity impacts may also occur from sedimentation in streams resulting from vegetation removal. The duration of the temporary construction impacts would vary depending on the recovery time required for the affected habitat type. For example, water quality impacts would be likely to occur over a small spatial and temporal extent because adherence to state water quality standards for turbidity requires implementation of BMPs to minimize the impact. Sound Transit also projected construction noise impacts on wildlife species within the study area described below and in Appendix H3.

Construction activities would also temporarily affect wildlife in the general area. Impacts would occur from losing vegetation and habitat, disrupting travel corridors, creating noise impacts, and displacing wildlife into potentially less suitable habitats where they might not thrive. Wildlife would likely be displaced when construction begins. Species displaced by construction noise would likely return after construction is complete if their habitat was not altered and if post-construction human activity levels return to pre-construction levels. However, reestablishing native vegetation would require 2 to 4 years for herbaceous upland and wetland types and decades for mature forest types. Species that forage on or near the ground, such as urban-dwelling small mammals or birds such as juncos and song sparrows, would use their preferred habitats first. Species that require mature vegetation, and especially those that use large shrubs and trees, such as wrens, chickadees, and woodpecker, would recolonize their preferred habitats last. Operational impacts could include permanent displacement of high-value habitat areas that can cause displacement of associated wildlife species, shading of vegetation, culvert extension, realignment of streams that support aquatic species, and additional runoff from increases in impervious surface area. Sound Transit also evaluated project operation noise levels above existing conditions and line-of-sight impacts that could lead to displacement or disturbance of wildlife species.

Sound Transit would implement BMPs to avoid and minimize impacts on streams and other aquatic habitats to meet federal, state, and local regulatory requirements. These BMPs are documented in Appendix H3 and are environmental commitments that Sound Transit would implement.

Sound Transit conducted surveys to prepare a Biological Assessment for ESA consultation. The determination of effect for ESA-listed species in Sound Transit's Biological Assessment is a "may affect, not likely to adversely affect" listed species, and there would be no adverse effect on Essential Fish Habitat under MSA.

4.8.3.1 No Build Alternative

The No Build Alternative would cause no temporary construction or permanent operational impacts on ecosystem resources. However, without the East Link Project, land use development might not be concentrated in the planned growth centers, causing additional growth elsewhere, including in or near areas of high-value habitat. Higher vehicle miles traveled also would be expected under the No Build Alternative, resulting in higher traffic, which can be associated with introducing more pollutants that might drain to surface waters and reduce water quality.

Implementing the No Build Alternative would not result in potential beneficial environmental improvements such as:

- Reducing pollutant loading to Lake Washington and streams in the study area by reducing 51.7

acres of pollutant-generating surfaces and an estimated 200,000 vehicle miles traveled each year

- Implementing proposed mitigation for wetlands and streams, which would improve the existing conditions of these resources.

4.8.3.2 Impacts during Operation

Impacts Common to All Build Alternatives

Permanent operational impacts common to all alternatives would depend on the ecosystem resource being affected (e.g., aquatic habitat from culvert extension or wildlife displacement from removal of high-value and priority habitat) and are described for each resource below. The following sections and Table 4.8-5 identify permanent operational impacts on high-value wildlife habitat, wetlands, wetland and stream buffers, and aquatic habitat.

High-Value Habitat

Several types of permanent impacts on habitat areas and impacts on associated wildlife would be expected:

- Habitat would be removed (particularly high-value habitat) that supports breeding, foraging, and roosting, which might disturb or even displace some wildlife species. Depending on the combination of alternatives selected, the range of impact (not including impacts on wetlands) could vary from 1.7 to 6.0 acres of high-value habitat removed within the study area before compensatory mitigation. Wildlife, including WDFW priority species that use this habitat type, might vacate the area.
- To prevent trees and branches from interfering with operation of the light rail, existing high-quality forest-dominated vegetation and wildlife habitat under and within 20 feet of each side of the elevated guideways would be converted to shrub and short-tree habitat, which may become high-quality habitat for some species.
- Existing low-quality, weed-dominated, and disturbed vegetation and wildlife habitat under and within 20 feet of each side of the elevated guideways would be converted to shrub and short-tree habitat, which would be a substantial environmental improvement.
- Operational noise impacts on wildlife would likely be relatively minor compared with existing traffic noise in most segments of the proposed corridors. Maximum noise levels from light rail operation would actually be lower than existing maximum noise levels related to other transportation noise sources currently in use in most segments, including heavy trucks, dump trucks, and buses.
- Existing maximum noise levels from buses and heavy trucks on busy arterials typically range from 78 to 86 decibels on the A-weighted scale (dBA) at 50 feet at 35 to 40 miles per hour (mph). The Link light rail trains produce 79 dBA at 50 feet at 40 mph, which is similar to the noise produced by most buses and medium trucks, and lower than heavy trucks by 2 to 6 dBA. Noise levels from East Link operations would not likely adversely impact wildlife for any segment because wildlife using habitats next to the alternatives are more or less accustomed to some level of existing human and vehicular activity.
- Linear disruption of habitat integrity. Losing small, interconnected habitats could increase habitat fragmentation in the area and disrupt wildlife movement between habitat types. In the project vicinity, many smaller habitat types were categorized as being low- or moderate-value habitats. These habitats could be used by a variety of wildlife species, including priority species, although their expected occurrence would be lower than for high-value habitats.
- The only ESA-listed wildlife species in the project vicinity, the marbled murrelet, is extremely rare in the study area (only one sighting in the past 50 years on Lake Washington) and is not expected to be adversely impacted from operations because there would not be any habitat alterations in Lake Washington, and the Segment A alternative would be located in the center of the I-90 roadway and not increase noise levels.
- Impacts on wetlands such as permanently removing wetland and steam buffer area and function, converting forest-dominated wetlands to shrub-dominated wetlands, and generating runoff from new untreated non- pollutant-generating impervious surfaces (PGIS) and new PGIS would also affect high value habitat.
- Potentially spilling fuel, oil, or chemical spills at maintenance facilities
- Beneficial environmental improvements listed above

Wetlands and Wetland Buffers

The alternatives were designed to avoid and minimize impacts on wetlands to reduce overall impacts. The alternatives would involve placing fill or retained cut/fill for at-grade tracks and columns for elevated guideways that could remove or shade wetlands. Permanent impacts on wetlands that would persist throughout East Link operation include the following:

TABLE 4.8-5
Potential Permanent Operational Direct Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Habitat

Alternative		**Wetland[a] (acres)**	**Wetland/ Stream Buffer[a,b] (acres)**	**High-Value Wildlife Habitat[a,c] (acres)**	**Aquatic Habitat/Stream Crossings[d]**
Segment A, Interstate 90					
Preferred Interstate 90 Alternative (A1)		No impacts			
Segment B, South Bellevue					
Preferred 112th SE Modified Alternative (B2M)	to *C11A*	0.1	3.3 (0.2 of mitigation site)	0.6	0 crossings
	to *C9T*		4.5 (0.2 of mitigation site)	0.7	1 crossing of a narrow alcove in the shoreline of Mercer Slough
Bellevue Way Alternative (B1)		0.2	1.8	1.7	0 crossings
112th SE At-Grade Alternative (B2A)			3.4 (<0.1 of mitigation site)	0.7	
112th SE Elevated Alternative (B2E)			2.8 (<0.1 of mitigation site)	0.4	
112th SE Bypass Alternative (B3)		0.7	3.4 (<0.1 of mitigation site)	0.7

114th NE Elevated Alternative (C14E)	from B3	<0.1	0.1	0	Same as C11A from B3
	from B3 – 114th Design Option or B7	0			Same as C11A from B7
Segment D, Bel-Red/Overlake					
Preferred NE 16th At-Grade Alternative (D2A) from former BNSF Railway corridor[f]		0.5	0.6	0.9	1 elevated crossing at the West Tributary to Kelsey Creek; 1 new culvert on a 130-foot segment on the Unnamed Tributary to Kelsey Creek
D2A - NE 24th Design Option		0.5	0.6	0.8	Same as *D2A*
NE 16th Elevated Alternative (D2E) from NE 12th or former BNSF Railway corridor		0.2 to 0.3	0.5	0.5	Same as *D2A* except the Unnamed Tributary to Kelsey Creek Crossing is elevated
NE 20th Alternative (D3) from NE 12th or former BNSF Railway corridor		0.2	0.1	<0.1 to 0.1	Same as *D2A* except for a culvert extension at Valley Creek (loss of 30 feet of channel function/habitat)
SR 520 Alternative (D5) from NE 12th or former BNSF Railway corridor		0.2 to 0.3	0.6 to 0.7	1.3 to 1.4	1 elevated crossing at West Tributary to Kelsey Creek, and Goff, and Valley Creeks culverts
Segment E, Downtown Redmond					
Preferred Marymoor Alternative (E2)		0.1 (0.1 of mitigation site)	0.4 (<0.1 of mitigation site)	1.1	2 elevated stream crossings (Sammamish River and Bear Creek)
E2 - Redmond Transit Center Design Option		0.1 (0.1 of mitigation site)	0.5 (<0.1 of mitigation site)	1.2	Same as *E2*
Redmond Way Alternative (E1)		0.1	0.2 (0.1 of mitigation site)	2.1	

TABLE 4.8-5 CONTINUED
Potential Permanent Operational Direct Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Habitat

Alternative	Wetland[a] (acres)	Wetland/ Stream Buffer[a,b] (acres)	High-Value Wildlife Habitat[a,c] (acres)	Aquatic Habitat/Stream Crossings[d]
Leary Way Alternative (E4)	<0.1	0.2 (0.1 of mitigation site)	1.2	
Maintenance Facilities				
116th Maintenance Facility (MF1) (D2A, D2E, D3)	0.1	0.1	0.1	0 stream crossings
116th Maintenance Facility (MF1) (D5)	0	0	0	0 stream crossings
BNSF Maintenance Facility (MF2) (D2A, D2E, D3)	0.1	0.1	0.1	Same as MF1 (D2A, D2E, D3)
BNSF Maintenance Facility (MF2) (D5)	0.1	0.2	0.2	0 stream crossings
SR 520 Maintenance Facility (MF3) (D2, D3, D5)	<0.1	0	0	2 culvert replacements with a gain of 42 feet of open channel on Goff Creek
SE Redmond Maintenance Facility (MF5)	0	0	0	0 stream crossings

[a] Vegetation areas were classified and mapped regardless of size or upland/wetland designation. As a result, the vegetation areas may include upland and/or wetland vegetation. Vegetation areas may overlap with wetlands and/or buffers, and therefore impact acreage numbers for wetlands, buffers, and high-value wildlife habitat cannot be added together. This overlap is depicted on Exhibits 4.8-1 to 4.8-4.

[b] Some of the impacts on stream buffers overlap with impacts on some wetland buffers.

[c] *High-Value Wildlife Habitat* includes riparian forest and three types of urban mostly vegetated forest (coniferous forest, deciduous forest, and mixed coniferous/deciduous forest).

[d] Stream crossings identified in this table are crossings of open channels. Crossings over existing culverts or piped sections of streams are not included.

[e] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

[f] Impacts for D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

- Permanently removing wetland area and function, including wetlands beneath elevated structures and portions of several existing mitigation sites. Depending on the combination of alternatives selected, impacts could vary from permanently filling or altering approximately 0.3 to 2.6 wetland acres.
- Permanently removing wetland and stream buffer area and function, including buffers beneath elevated structures. Depending on the combination of alternatives selected, impacts could vary from permanently filling or altering approximately 0.8 to 5.6 acres of wetland/stream buffer.
- Permanently converting forest-dominated wetlands to shrub-dominated wetlands and buffers under and within 20 feet of each side of the elevated guideways to prevent trees and branches from interfering with operation of the light rail.
- Generating runoff from new untreated non-PGIS and new PGIS (i.e., roadway modifications, park-and-ride lots, and maintenance facilities), potentially increasing pollutant loads to wetlands (see Section 4.9, Water Resources)
- Potentially spilling fuel, oil, or chemical spills at maintenance facilities
- Beneficial environmental improvements listed above

Aquatic Habitat

The range of permanent impacts would vary from no impacts on fish habitats, to beneficial impacts, to only minor adverse impacts before mitigation. In urban areas, new projects may result in beneficial impacts on aquatic resources. New projects that alter streams would have to meet current regulatory requirements on stream restoration, including improving instream habitat and improving riparian vegetation. Permanent impacts on aquatic habitat common to all alternatives would include the following:

- Impervious surfaces preclude normal infiltration of precipitation into groundwater aquifers and reduce dry-season base flows by decreasing water inputs to streams from springs and seeps. The amount of new impervious surface that could result from building the East Link Project between Seattle and Redmond would be between 16 and 35 acres (see Section 4.9, Water Resources).

- Stormwater from all project-related PGIS would be treated to at least basic treatment levels (i.e., removal of at least 80 percent of suspended solids). Stormwater from relocated or widened roadways and those that do not currently receive treatment would also be retrofitted to current standards. Stormwater from maintenance facilities would be treated to enhanced treatment levels to remove heavy metals, including those that are toxic to fish and aquatic invertebrates. Basic and enhanced treatment would reduce heavy metal and hydrocarbon contaminants in stormwater but would not eliminate all of it. In addition, the East Link Project would result in fewer cars on the road and, therefore, less pollutant loading to stream systems. Substantial permanent impacts on water quality, and therefore aquatic species, would not be expected from increased surface runoff.

Permanent Operational Impacts by Alternative

Segment A

With *Preferred Alternative A1,* removing motor vehicles from the center roadway would reduce the pollutant discharge from this roadway, resulting in a net benefit to the water quality of stormwater runoff to Lake Washington. Operation of light rail could discharge stray electrical current into Lake Washington and create electric current fields around the span. An assessment of whether the electric current field would affect aquatic resources estimated that stray current intensity would be one to three orders of magnitude below physiological or behavioral response thresholds for even the most sensitive Lake Washington fish species. Therefore, no operational impacts on high-quality aquatic habitats are anticipated due to this factor.

Segment B

High-Value Habitat

Preferred 112th SE Modified Alternative (B2M) connecting to *Preferred 108th NE At-Grade Alternative (C11A)* or *Preferred 110th NE Tunnel Alternative (C9T)* would permanently affect 0.6 and 0.7 acre of high-value habitat, respectively (all deciduous forest), which would be slightly higher than the smallest total impact among the Segment B alternatives. This impact includes removing some mature deciduous trees near the Bellevue Way SE and 112th Avenue SE intersection.

With the other Segment B alternatives, the potential area of high-value habitat that could be permanently impacted varies from approximately 0.4 acre (112th SE Elevated Alternative [B2E]) to approximately 3.0 acres (BNSF Alternative [B7]). Alternative B7 would affect the most area of riparian forest. Alternatives B1 and B7 would affect the most high-value coniferous forest. Alternative B7 would affect the largest area of high-value deciduous forest (0.8 acre), which exceeds the total amount of high-quality wildlife habitat that would be affected by *Preferred Alternative B2M.* Amphibians are not expected to move from Mercer Slough to uplands west of Bellevue Way SE and are also not expected to be impacted because Bellevue Way is already a barrier.

Wetlands and Wetland Buffers

Preferred Alternative B2M would be located along the east side of Bellevue Way SE and 112th Avenue SE where Mercer Slough is located, but *B2M* almost entirely avoids permanent impacts on wetlands (approximately 0.1 acre). However, *Preferred Alternative B2M to C9T* would have the largest impact on wetland buffers of all the Segment B alternatives.

Portions of *Preferred Alternative B2M* would be constructed in retained cuts along Bellevue Way SE. Without mitigation, the concrete-lined retained cuts could intercept and re-direct local groundwater flow, with resulting adverse impacts to down-gradient wetlands and surface water features. As described in the Water Resources mitigation section (Section 4.9.4), the pervious fill system installed around the outside of the sealed, concrete-lined retained cut would allow the shallow groundwater to continue to flow to the down-gradient wetlands. Similarly, track foundations in many places along this section would be improved with subsurface stone columns, but these are pervious to groundwater movement. The primary sources of hydrology for the Mercer Slough wetlands are the controlled water fluctuation of Lake Washington; input from Kelsey Creek and other small drainages; groundwater from the hillside slopes to the west and east of Mercer Slough wetlands; culverts that enter from the north, west, and east sides; and precipitation. As a result, no impact on hydrology of the Mercer Slough wetland is expected.

Of the other Segment B alternatives, Alternative B7 could have the greatest permanent impact on wetlands (1.9 acres). Nearly one-quarter of this impact would be on existing mitigation sites. Alternative B7 would have the smallest permanent impact on wetland buffers (0.4 acre).

The other Segment B alternatives along Bellevue Way SE (Bellevue Way Alternative [B1], 112th SE At-Grade Alternative [B2A], and B2E) would all permanently affect approximately 0.2 acre of wetland with the new stormwater pond proposed immediately east of the

South Bellevue Park-and-Ride Lot. All of these Segment B alternatives would avoid permanent wetland impacts on existing mitigation sites within the Mercer Slough Nature Park.

The 112th SE Bypass Alternative (B3) could potentially impact 0.7 acre of wetlands. This alternative would have similar impacts on wetlands along Bellevue Way SE as the other Bellevue Way alternatives. However, constructing the elevated guideway through the Sturtevant Creek Wetland (WR-3) would also disturb 0.5 acre of shrub and emergent Category 2 wetlands dominated by reed canarygrass (a state-listed noxious weed). Implementing Alternative B3 - 114th Extension Design Option with Alternative B3 would reduce the potential permanent operational impacts on wetlands or buffers by avoiding the Sturtevant Creek Wetland (WR-3).

The other Segment B alternatives would have varying degrees of potential permanent impacts on wetland/stream buffers. Among the Segment B alternatives along Bellevue Way SE, Alternative B1 would have the least permanent impacts on wetland/stream buffers (1.8 acres). All Bellevue Way alternatives except Alternative B1, including *Preferred Alternative B2M*, would have relatively similar potential permanent impacts on buffers. All of these Segment B alternatives (except B1) would permanently impact wetland buffers of existing mitigation sites within the Mercer Slough Nature Park.

Aquatic Habitat

Preferred Alternative B2M to either *C11A* or *C9T* would have a small direct permanent impact on aquatic habitat. *Preferred Alternative B2M* would install a short bridge over a small unnamed stream inlet to Mercer Slough West near SE 15th Street. Impacts on the stream buffer between the west channel of Mercer Slough and 112th Avenue SE are estimated at 0.4 and 1.0 acre for *Preferred Alternative B2M to C11A* or *C9T*, respectively. The vegetation in this stream buffer that would be affected is low-quality habitat because it is dominated by Himalayan blackberry (a state-listed noxious weed) and mowed lawn with few native trees or shrubs (Exhibit 4.8-5).

The other Segment B alternatives (Alternatives B1, B2A, B2E, B3, B3 – 114th Design Option, and B7) would have no direct permanent impacts on fish and aquatic habitats. Of all the Segment B alternatives, the B3 – 114th Design Option and Alternative B7 would have the greatest impact on stream buffer.

11/09/2009 16:42

EXHIBIT 4.8-5
Mercer Slough Buffer along 112th Avenue SE

Segment C

High-Value Habitat

Preferred Alternative C11A would not have permanent impacts on high-value wildlife habitat. *Preferred Tunnel Alternative C9T* would have minor permanent impacts (0.3 acre) on high-value wildlife habitat in Segment C just south of SE 6th Street.

With the 106th NE Tunnel (C2T), 108th NE Tunnel (C3T), Couplet (C4A), 112th NE Elevated (C7E), and 110th NE At-Grade (C9A) Alternatives, there would be a relatively small area of permanent impacts on high-value wildlife habitat (less than 0.1 to 0.2 acre). The other Segment C alternatives would have no impact.

Wetlands and Wetland Buffers

No direct or indirect permanent impacts on wetlands or wetland/stream buffers are expected from either *Preferred Alternative C11A* or *C9T* when connected to *Preferred Alternative B2M*. The connection of either *Preferred Alternative C11A* or *C9T* to Alternatives B3, B3-114th Design Option, or B7 would result in a 0.1 acre wetland/stream buffer impact.

Alternatives C9A and C14E would have a less than 0.1 acre direct permanent impact on wetlands when connecting to B3. No other Segment C alternatives would result in direct permanent impacts on wetlands. No direct permanent impacts on wetland buffers are expected from the other Segment C alternatives, except the 0.1 acre impact to wetland buffers at the Hilton Stormwater pond (WR-16) noted above. This same impact would occur for Alternatives C2T, C3T, C4A, C7E, 110th NE Elevated (C8E), C9A, and 114th NE Elevated (C14E) with connections to either Alternatives B3, B3- 114th Design Option, or B7.

Aquatic Habitat

Identical potential impacts would result with *Preferred Alternatives C11A* and *C9T* (both from *Preferred Alternative B2M*). The Hospital Station would be positioned over the top of the existing Sturtevant Creek channel just north of NE 8th Street (Exhibit 4.8-6). To minimize impacts on the stream and provide for overall improved stream geometry, the channel would be shifted to the west side of the tracks in the former BNSF Railway corridor in a new culvert, thereby realigning the channel to the west approximately 30 feet as an open channel in a landscaped strip next to the station. This reach is approximately 300 feet long. The new channel would be a substantial improvement compared to the existing channel, which is straight, featureless, and lacking any riparian vegetation. The new channel would have landscaped riparian vegetative cover, a gravel streambed, and a curving geometry. However, there is no salmonid presence in this reach because the reach is upstream of several fish-passage blockages.

For connections from Alternative B3 and *Preferred Alternatives C11A* or *C9T* would run near Sturtevant Creek for 420 feet adjacent to the Hilton Hotel. The existing vegetation along this stream reach would be cleared during construction and replanted with short-growing native species (Exhibit 4.8-7). The elevated guideway would be up to 45 feet above the ground and not effectively shade this riparian area. There would be a temporal loss of riparian function while the new riparian trees reestablish. Even though the riparian trees would be smaller, large woody debris recruitment potential would not be diminished because this area is an intensively managed landscape.

Preferred Alternatives C11A or *C9T* connecting from the B3 – 114th Design Option or Alternative B7 would have the same impacts as described above for the Alternative B3 connector but would add approximately 300 feet of clearing (total of 720 feet), and 130 feet of guideway above the channel, approximately 25 feet off the ground. Potential impacts on riparian function would be the same as described above for this additional reach, except that landscaping in this area is not actively managed to the water's edge as it is on the Hilton Hotel property.

Alternatives C3T, C4A, and C7E connecting from Alternative B2E would have no impact on aquatic habitat and, thus, have the least impacts of all Segment C alternatives. The Bellevue Way Tunnel Alternative (C1T), Alternative C2T, and Alternative C9A from Alternatives B2A or B1, would have the same impacts described for *Preferred Alternatives C11A* and *C9T*.

EXHIBIT 4.8-6
Sturtevant Creek upstream of NE 8th Street

09/25/2009 12:32

EXHIBIT 4.8-7
Sturtevant Creek next to Hilton Hotel at 114th Avenue SE

Alternatives C2T and C9A from Alternative B3, B3 - 114th Design Option, or B7 would have the same impacts as *Preferred Alternatives C11A* or *C9T* for both the Hospital Station and the area behind the Hilton Hotel along Sturtevant Creek.

Segment D

High-Value Habitat

Preferred NE 16th At-Grade Alternative (D2A) and Alternatives D2A – 120th Station and - NE 24th Design Options would permanently impact approximately 0.8 to 0.9 acre of high-value habitat, including mostly riparian forest and deciduous forest. There would be no impact on vegetation and wildlife related to the storage track or associated improvements to the former BNSF Railway corridor with *Preferred Alternative D2A.*

The estimated area of high-value habitat that would be directly affected during permanent operation with the other Segment D alternatives varies from a low of approximately <0.1 acre (NE 20th Alternative [D3]) to a high of approximately 1.3 to 1.4 acres (SR 520 Alternative [D5]) depending on connection). Alternative D5 would affect the most area of riparian forest, coniferous forest, and deciduous forest.

Wetlands and Wetland Buffers

Preferred Alternative D2A would have permanent operational impacts on wetlands WR-11 and WR-15 (resulting from fill for the at-grade trackway), and wetlands WR-7 and WR-8SE where the elevated guideway would cross over. Potential permanent operational impacts on wetlands and wetland buffers would be 0.5 and 0.6 acre, respectively. This is a small permanent operational impact on these Category 3 and 4 wetlands. The primary impact would be on Wetland WR-7, which is a regional stormwater detention pond. Impacts on wetlands and wetland buffers from both D2A design options would essentially be the same as with *Preferred Alternative D2A*.

The storage track along the former BNSF Railway corridor north of the Lake Bellevue would result in impacts of less than one-eighth of an acre of wetland and one-tenth of an acre wetland buffer to accommodate an access path adjacent to the storage tracks.

The other Segment D alternatives and connection options would have approximately one-half the permanent operational impacts on wetlands compared to *Preferred Alternative D2A,* primarily because they would avoid impacts on wetland WR-7. The NE 16th Elevated Alternative (D2E) would permanently affect 0.2 to 0.3 acre of wetland (depending on connection) due to the elevated guideway over Wetlands WR-6, WR-8SE, WR-11, and WR-15. Alternative D3 would permanently affect 0.2 acre of wetland as a result of fill used to widen 136th Place NE for the at-grade trackway at WR-15 and the elevated guideway over Wetlands WR-6 and WR-8SE. Alternative D5 would permanently affect 0.2 to 0.3 acre of wetland (depending on connection) from the elevated guideway over Wetlands WR-6, WR-8NW, and WR-11. Potential permanent impacts on wetland/stream buffers would be lowest (0.1 acre) with Alternative D3 and slightly greater with Alternatives D2E and D5.

Aquatic Habitat

Preferred Alternative D2A would cross four streams but would have negligible or no direct permanent impact on fish and aquatic species and habitats on these streams.

EXHIBIT 4.8-8
West Tributary to Kelsey Creek at Detention Pond

The elevated crossing at the Kelsey Creek West Tributary would place approximately five support columns along the southern edge (left side of Exhibit 4.8-8) of the regional stormwater detention pond (wetland WR-7). The pond does not support salmonids because there are numerous passage blocks downstream and no spawning areas upstream. This area is artificially flooded by the stormwater detention facility; sometimes this area is dry. Large trees would be removed and replaced with understory vegetation. The elevated guideway would be approximately 55 feet in the air.

During operation of *Preferred Alternative D2A*, there would be no permanent impacts on Goff Creek at this at-grade crossing because the creek is in a pipe system at this location.

Direct permanent impacts on the Unnamed Tributary to Kelsey Creek would result from replacing 130 feet of open channel with a culvert for this at-grade crossing. The existing stream channel is essentially a roadside ditch with no riparian vegetation other than mowed grasses. This tributary does not currently support fish. This reach has no habitat function except, perhaps, nutrient uptake. Therefore impacts would be negligible.

Operating *Preferred Alternative D2A* would not result in any permanent impacts on Valley Creek at this elevated crossing because it is in a culvert at this location. Both D2A design options would have potential impacts identical to that of *Preferred Alternative D2A*. The proposed storage track (located between the potential maintenance facilities MF1 and MF2) would not have any impact on aquatic habitats.

The *City of Bellevue Bel-Red Corridor Project Final Report* (September 2007) identifies the West Tributary to Kelsey Creek and Goff Creek as having the greatest opportunity for stream enhancement. The East Link Project would not preclude these enhancements.

Alternative D2E would have no direct permanent impact on the West Tributary to Kelsey Creek.

Alternative D2E is shifted slightly southward to avoid the regional stormwater detention pond and instead spans West Tributary to Kelsey Creek as an elevated guideway 50 to 60 feet off the ground at this location. Impacts at Goff Creek, the Unnamed Tributary to Kelsey Creek, and Valley Creek would be the same as that described for *Preferred Alternative D2A*.

Alternative D3 would have similar impacts as Alternative D2E, except there would be direct permanent impacts where Alternative D3 crosses Valley Creek along NE 20th Street. Aquatic and riparian functions would be lost for the 30 linear feet of channel enclosed in the lengthened culvert at 20th Street. This reach of Valley Creek was rated as good habitat. Sears Creek would be unaffected because it is piped at this location and the proposed retained cut would not cut deep enough to affect the pipe.

Alternative D5 would have impacts at the West Tributary to Kelsey Creek similar to those described for *Preferred Alternative D2A* and Alternative D2E. Impacts at Goff Creek and Valley Creek would be the same as described for *D2A* at Valley Creek. The Unnamed Tributary to Kelsey Creek would be crossed where it is in a pipe system.

Segment E

High-Value Habitat

Preferred Alternative E2 and Alternative E2 - Redmond Transit Center Station Design Option would permanently affect approximately 1.1 and 1.2 acres, respectively, of high-value coniferous and deciduous forest next to SR 520.

The estimated area of high-value habitat that would be directly affected during East Link operation by the other Segment E alternatives is approximately 1.2 acres with Leary Way Alternative (E4) and approximately 2.1 acres for Redmond Way Alternative (E1) (which is nearly twice the impact as from the *Preferred Alternative E2*). Alternative E1 would impact the high-value coniferous forest.

Wetlands and Wetland Buffers

Preferred Alternative E2 could permanently impact up to 0.1 acre of wetland and 0.4 acre of wetland/stream buffer. *Preferred Alternative E2* would affect the existing mitigation wetland and buffers at Marymoor Park Wetland (WR-13) and the wetland and stream buffer at the railroad crossing at the Bear Creek Wetland (WR-12). Impacts would be only slightly higher with the E2 - Redmond Transit Center Design Option (see Table 4.8-5).

The other Segment E alternatives (E1 and E4) would have impacts on wetlands and wetland buffers comparable to *Preferred Alternative E2*.

Aquatic Habitat

Preferred Alternative E2 would have little direct permanent impacts on aquatic species and habitat. *Preferred Alternative E2* would affect riparian vegetation at the Sammamish River crossing by replacing taller growing tree species with lower understory riparian plants. There would be some shading impacts on approximately 5 feet of streambank and channel on either side of the existing former BNSF Railway Bear Creek railroad bridge. There would be no impact on aquatic habitat from the E2 - Redmond Transit Center Design Option.

Alternative E1 would have the same impacts as *Preferred Alternative E2* at the Sammamish River crossing except that more (0.2 acre) riparian vegetation would be affected. At the Bear Creek crossing, there would be no impacts on riparian vegetation because the guideway would be 48 feet above the top of the stream bank and 53 feet above the water surface. No tall growing tree species are present at this location.

Alternative E4 would have the same impacts as *Preferred Alternative E2* at the Sammamish River crossing. Impacts on the riparian community would be similar to *Preferred Alternative E2* at the Bear Creek crossing except with a higher elevated crossing.

Maintenance Facilities

Table 4.8-5 shows potential permanent operational impacts from maintenance facilities. The three maintenance facilities in Segment D (MF1, MF2, and MF3 maintenance facilities) would require wetlands and/or wetland buffers to be filled. MF3 would result in an increase of 42 linear feet of open stream channel by replacing two culverts with shorter ones on Goff Creek. No permanent operational impacts are expected from the MF5 in Segment E.

4.8.3.3 Construction Impacts

Impacts Common to All Build Alternatives

The following summarizes potential temporary impacts that could occur throughout the study area during construction:

- Impacts on vegetation and wildlife habitat:
  - Loss and degradation of breeding, foraging, and roosting habitat
  - Temporary wildlife displacement and disturbance from construction activity noise
  - Movement of mobile species to adjacent areas where they may or may not survive,

  - depending on the availability of nearby suitable and available habitat
  - Loss of less mobile species and species that retreat to burrows
- Impacts on wetlands and buffers:
  - Temporary disturbance of wetland area and function, including wetlands beneath elevated structures. Depending on the combination of alternatives selected, the range of impact could vary from 0.8 to 4.9 acres of wetland.
  - Vegetation clearing, site grading, and filling for construction access to permanent facilities
  - Soil compaction during construction activities that decreases soil permeability, infiltration, water-storage capacity, and vegetation regrowth
  - Reduction of wetland functions
  - Potential accidental spills of fuel oils, chemicals, and/or concrete leachate used during construction
  - Some increase in sediment loading and turbidity from grading and filling activities that could allow sediment-laden runoff into wetlands and degrade water quality
  - Potential introduction and spread of invasive species as a result of disturbance where weeds do not already exist
- Impacts on aquatic habitat:
  - Sedimentation impacts on waters downstream from earthwork activities
- Clearing of riparian vegetation at stream crossings

Removing high-value habitat can affect wildlife resources, and noise from construction activities can also affect wildlife presence, breeding, and foraging habitats. Noise from typical construction activities for light rail construction can range from 80 to 94 dBA Lmax within 50 feet. Typical construction noise is similar from roadway construction and light rail construction. Pile driving could produce 105 to 110 dBA maximum noise level (Lmax). Loud noises from short-term events such as these can startle nearby wildlife and agitate birds. Most wildlife normally return to their usual lifestyle shortly after the event, depending on duration, species, and proximity of the wildlife to the construction activity. The East Link Project would require no in-water work activity that would generate sound pressure levels that would impact threatened and endangered fish species.

Some wetlands and wetland/stream buffers would be temporarily impacted. Protective fencing would be installed to establish construction limits to minimize impacts in this area during construction, and impacted wetland and wetland buffer would be restored after construction.

Any construction activities requiring work below the ordinary high water mark in water bodies supporting fisheries resources would comply with USFWS-, NMFS-, and WDFW-established construction in-water work windows for protection of fish species, including ESA-listed species. Although a detailed construction schedule has not been developed yet, the allowable construction work window should not affect overall project schedule. See Table 4.8-6 for likely in-water work windows for the resources in the study area. Final work windows would be determined during permitting.

TABLE 4.8-6
In-Water Construction Work Windows for Listed Species[a]

Water Body	Applicable Alternative	ESA Work Window
Lake Washington (western and eastern highrises of I-90 floating bridge)	*Preferred Alternative A-1*	July 16 through December 31
Lake Washington (East Channel Bridge)	*Preferred Alternative A-1*	July 16 through July 31; November 16 through December 31
Kelsey Creek Watershed	All Segment D and Segment E Alternatives	July 1 through August 31
Sammamish River and lower Bear Creek	All Segment E Alternatives	July 16 through July 31; November 16 through March 15

[a]Final work windows would be determined during permitting

Temporary Construction Impacts by Alternative

Table 4.8-7 shows potential temporary construction impacts on wetlands, wetland/stream buffers, high-value wildlife habitat, and aquatic habitat that would occur as a result of the East Link Project. Specific impacts are described in the following sections.

Segment A

Several priority species that use Lake Washington in the vicinity of the I-90 bridge may temporarily avoid the bridge area as a result of construction noise. The construction of East Link may have impacts on avian species, such as impacts on the peregrine falcon nests. WSDOT is currently modifying portions of I-90; no impacts on avian species have been reported as result of this activity, and WSDOT has been monitoring the success and failure of the two nests.

TABLE 4.8-7
Potential Temporary Construction Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Resources

Alternative		**Wetland[a] (acres)**	**Wetland/ Stream Buffer[a,b] (acres)**	**High-Value Wildlife Habitat[a,c] (acres)**	**Aquatic Resources**
Segment A, Interstate 90					
Preferred Alternative A1		0	0	0	Over-water and in-water work in Lake Washington
Segment B, South Bellevue					
Preferred Alternative B2M	*to C11A*	0.5 (<0.1 of mitigation site)	4.0 (0.2 of mitigation site)	1.1	Potential sedimentation from construction of crossing at storm drain channel (near "Y" at Bellevue Way and 112th) and crossing of a narrow alcove off of Mercer Slough (near SE 15th Street)
	to C9T		3.7 (0.2 of mitigation site)	1.0	
Alternative B1		0.9	3.0 (0.3 of mitigation site)	2.1	None
Alternative B2A		0.7	3.7 (0.3 of mitigation site)	1.9	
Alternative B2E		0.6	3.5 (0.3 of mitigation site)	1.3	
Alternative B3		1.2	3.9 (0.3 of mitigation site)	1.9	
B3 – 114th Design Option		0.6	4.8 (0.3 of mitigation site)	2.4	Potential sedimentation from construction of elevated crossing over Sturtevant Creek
Alternative B7		2.9 (0.7 of mitigation site)	0.6 (<0.1 of mitigation site)	4.6	Potential sedimentation from construction of elevated crossing over Mercer Slough
Segment C, Downtown Bellevue					
Preferred Alternative C11A	from *B2M*	0	0	<0.1	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing
	from B3, B3 – 114th Design Option, or B7		0.1	0	
Preferred Alternative C9T[d]	from *B2M*	0	<0.1	0.2	Potential sedimentation from construction in the Sturtevant Creek channel. Vegetation clearing
	from B3 from B3 – 114th Design Option or B7		0.1	0	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing
Alternative C1T		0	0	0	None
Alternative C2T	from B2A or B2E	0	0	0	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing
	from B3 or B7		0.1		
Alternative C3T	from B2A or B2E	0	0	0	None
	from B3 or B7		0.1		Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing
Alternative C4A	from B2A or B2E	0	0	0	None
	from B3 or B7		0.1		Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing
Alternative C7E	from B2A or B2E	0	0	0	None
	From B3 or B7		0.1		Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing.
Alternative C8E	from B3 or B7	0	0.1	0	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing.
Alternative C9A	from B2A	0	0	0.2	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing.
	from B3	0.1	0.1	0	
	from B3 – 114th Design Option or B7	0			
Alternative C14E	from B3	0.1	0.1	0	Potential sedimentation from construction close to and in the Sturtevant Creek channel. Vegetation clearing.
	from B3 – 114th Design Option or B7	0			

TABLE 4.8-7 CONTINUED
Potential Temporary Construction Impacts on Wetland, Wetland/Stream Buffer, High-Value Wildlife Habitat, and Aquatic Resources

Alternative	Wetland[a] (acres)	Wetland/ Stream Buffer[a,b] (acres)	High-Value Wildlife Habitat[a,c] (acres)	Aquatic Resources
Segment D, Bel-Red/Overlake				
Preferred Alternative D2A from former BNSF Railway corridor[e]	0.5	1.7	1.9	Potential sedimentation from in-water construction in the West Tributary to Kelsey Creek and the Unnamed Tributary to Kelsey Creek. Construction near Valley Creek. Vegetation clearing.
D2A – NE 24th Design Option			2.0	
Alternative D2E from NE 12th or former BNSF Railway corridor	0.2 to 0.3	0.6 to 0.7	0.7 to 0.8	Potential sedimentation from construction near West Tributary to Kelsey Creek, the Unnamed Tributary to Kelsey Creek, and Valley Creek. Vegetation clearing
Alternative D3 from NE 12th or former BNSF Railway corridor	0.1	0.1 to 0.2	0.2 to 0.3	Potential sedimentation from construction near West Tributary to Kelsey Creek and in-water construction in Valley Creek and the Unnamed Tributary to Kelsey Creek. Vegetation clearing.
Alternative D5 from NE 12th or former BNSF Railway corridor	0.4	0.8	1.2 to 1.3	Potential sedimentation from construction near West Tributary to Kelsey Creek, Goff Creek, and Valley Creek.
Segment E, Downtown Redmond				
Preferred Alternative E2	0.1 (<0.1 of mitigation site)	0.9 (0.4 of mitigation site)	1.5	Potential for sedimentation from construction near the Sammamish River and Bear Creek. Vegetation clearing
E2 - Redmond Transit Center Design Option	0.2 (<0.1 of mitigation site)	0.9 (0.3 of mitigation site)	1.6	
Alternative E1	0.1	0.3 (0.1 of mitigation site)	2.1	
Alternative E4	<0.1	0.2 (0.1 of mitigation site)	1.1	

[a] Vegetation areas were classified and mapped regardless of size or upland/wetland designation. As a result, the vegetation areas may include upland and/or wetland vegetation. Vegetation areas may overlap with wetlands and/or buffers, and therefore impact acreage numbers for wetlands, buffers, and high-value wildlife habitat cannot be added together. This overlap is depicted on Exhibits 4.8-1 to 4.8-4.

[b] Some of the impacts on stream buffers overlap with impacts to some wetland buffers.

[c] *High-Value Wildlife Habitat* includes riparian forest and three types of urban mostly vegetated forest (coniferous forest, deciduous forest, and mixed coniferous/deciduous forest).

[d] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

[e] Impacts for D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

Most of the rest of Lake Washington provides comparable suitable habitat for all of the species that may temporarily avoid the project vicinity, and no measureable impacts are expected. Automobiles would be removed from the center lanes of I-90; therefore, no new pollutants would run off from this portion of the bridge.

Sound Transit may to implement special seismic upgrades to the I-90 floating bridge during the construction period. This would include in-water work in Lake Washington to reinforce the structure (see Table 4.8-6 for allowable in-water work windows that Sound Transit would use). The in-water work would consist of bolting or welding the East Channel bridge support column reinforcement jackets together. Impacts from this would be negligible and thus, work isolation BMPs would not be necessary here.

Additionally, construction activities to modify the existing I-90 bridge to accommodate the rail may involve grinding concrete, which could result in concrete dust entering Lake Washington. The lime found in concrete is alkaline, so when concrete comes into contact with water, the water becomes strongly alkaline (pH 11 to 13). High pH can be toxic to fish. Inadvertent spills could affect water quality and aquatic resources. Implementation of BMPs (see Sections 4.9, Water Resources, and 4.12, Hazardous Materials) would avoid and minimize the introduction of concrete dust and accidental spills into the lake. The East Link construction activities in this segment would have a low risk of impacts on ESA-listed fish.

Some work and equipment may be located on a barge in Lake Washington adjacent to the bridge sections. A tribal fishery sometimes occurs in July or August for sockeye, and a tribal fishery may occur at other times for other species in the future. Sound Transit would contact and coordinate with the Muckleshoot Tribe before construction begins on the I-90 bridge so that support boats and barges would not interfere with tribal fisheries.

Segment B

High-Value Habitat

Preferred Alternative B2M would temporarily impact 1.0 to 1.1 acres, depending on the connection to *Preferred Alternative C11A* or *Preferred Alternative C9T*, of high-value deciduous forest habitat, which includes the removal of some mature deciduous trees near the Bellevue Way SE and 112th Avenue SE intersection. Impacts on this area would be minimized to the maximum extent possible, by limiting clearing of mature vegetation to the construction area on each side.

Noise and construction activity in all Segment B alternatives, including *Preferred Alternative B2M*, would have the potential to temporarily displace wildlife in the Mercer Slough Nature Park because construction noise would extend into the parklands. Impacts would be relative to changes in noise levels and the types of human activities. Comparable temporary replacement habitats do not exist in the project vicinity.

WDFW priority species that may use Mercer Slough and forested stands for foraging include the bald eagle, pileated woodpecker (*Dryocopus pileatus*), green heron (*Butorides virescens*), and willow flycatcher (*Empidonax traillii*), which are all relatively sensitive to human disturbance and habitat alteration. Temporary losses of these high-value habitat types would occur. These losses may affect foraging, breeding, and roosting behavior and temporarily displace these species from the project vicinity. Although specific bald eagle foraging locations are not known, construction in Segment B could temporarily displace eagles foraging in the area. Due to the amount of similar available habitat in the Mercer Slough Nature Park, impacts on wildlife would not be substantial. Western toad (*Bufo boreas*) is the only priority species with limited mobility identified as potentially occurring in the study area. If western toads are present close to the construction area during the mating season (spring), construction noise associated with all Segment B alternatives could interfere with the western toad's ability to hear mating and alarm calls and disrupt its reproduction or survival.

With the Segment B alternatives other than *Preferred Alternative B2M*, the estimated area of high-value habitat that would be directly affected during clearing for construction would vary from approximately 1.3 acres (Alternative B2E) to approximately 4.6 acres (Alternative B7). Alternative B7 would affect more area of each high-value habitat than any other Segment B alternative. All the Bellevue Way alternatives would have a similar total impact on high-value wildlife habitat as Alternative B2E.

Wetlands and Wetland Buffers

Preferred Alternative B2M to either *C11A* or *C9T* would temporarily impact 0.5 acre of Category 2 wetland that is located next to Bellevue Way SE and 112th Avenue SE (WR-1/2). This is the lowest temporary wetland impact of the Segment B alternatives. The potential temporary impacts on wetlands would be primarily related to the following:

- Construction staging and access within the construction corridor east of the permanent Sound Transit right-of-way along Bellevue Way SE and 112th Avenue SE.
- Construction staging near the South Bellevue Park-and-Ride Lot, which would affect a portion of the Mercer Slough Wetland (WR-1/2), including modifications to the existing stormwater pond.

The potential temporary impacts on wetland buffers would be 4.0 and 3.7 acres for connections to *Preferred Alternatives C11A* or *C9T,* respectively (see Table 4.8-7). general condition of the wetland buffers affected by construction includes unvegetated areas as well as areas of blackberry, lawn, and some deciduous forest (often with an understory of weeds such as Himalayan blackberry and patches of Japanese knotweed). The potential temporary impacts on wetland buffers would be primarily related to the following:

- Construction near the South Bellevue Park-and-Ride Lot
- Construction of the elevated guideway near the intersection of Bellevue Way SE and 112th Avenue SE, which would affect an area of deciduous forest with high-quality habitat
- Construction staging and access within the area east of the project right-of-way

Included are construction impacts on an existing mitigation site located immediately south of the South Bellevue Park-and-Ride Lot. Restoring these affected buffers after construction could improve buffer function by replacing existing areas that are dominated by noxious and invasive weeds or lawn with native species. This could improve the functions of the existing wetland and stream buffers and result in a beneficial environmental impact. Of the other Segment B alternatives, Alternative B7 would have the greatest temporary construction impacts on wetlands and high-value habitat.

Of all the alternatives evaluated, Alternative B7 has the potential for the largest temporary impact on wetlands (2.9 acres, see Table 4.8-7). The majority of this impact would result from crossing the Mercer Slough wetland (WR-1/2). Alternative B7 would also bisect the WSDOT 118th Avenue SE wetland (WR-5). In order to construct the elevated guideway across Mercer Slough, a temporary work trestle might need to be built. The option of constructing the guideway with an overhead gantry could reduce temporary impacts and would be explored during final design. Alternative B7 would have the lowest potential temporary impact on wetland buffers of all the Segment B alternatives.

Alternatives B1, B2A, and B2E would have relatively similar and low potential impacts on wetlands and similar potential impacts on wetland/stream buffers. These alternatives would also have relatively similar potential buffers impacts that would primarily affect wetland/stream buffers along 112th Avenue SE, which consist of disturbed vegetation dominated by Himalayan blackberry (see Exhibit 4.8-5). Alternatives B1, B2A, B2E, and B3 (with and without the B3 - 114th Design Option) would avoid wetland impacts on existing mitigation sites.

The B3 - 114th Design Option would avoid the temporary impact (approximately 0.6 acre) that Alternative B3 would have on the Sturtevant Creek wetland. This design option would include several small impacts on wetlands near the shoreline of Mercer Slough West, and involve an elevated crossing of Sturtevant Creek along the south side of SE 8th Street that might temporarily affect streamside wetlands and buffers.

Aquatic Habitat

Preferred Alternative B2M to C9T would have no direct temporary impacts on fish and aquatic species and habitats. It could have some indirect temporary impacts. *Preferred Alternative B2M* would be closer to Mercer Slough West than the other alternatives, and thus would have the highest risk of adding sediment to the slough compared with the other alternatives in Segment B. It also may result in vegetation clearing to the water's edge, causing temporary impacts on riparian zone function. *Preferred Alternative B2M to C11A* is similar to *B2M to C9T* but would be set farther away from Mercer Slough. Except for Alternative B7, the construction impacts of the other Segment B alternatives would have aquatic habitat impacts similar to *Preferred Alternative B2M*. The differences lie in the proximity to Mercer Slough. Other alternatives that follow Bellevue Way SE are farther from Mercer Slough and thus would have a smaller risk of impacts on aquatic habitat. Construction activities in this segment would have a low risk of impact on salmonids because there is no spawning or primary rearing habitat and there would be no in-water work.

Alternative B7 would cross Mercer Slough with a free-spanning structure, and the support columns would be located outside of the ordinary high water mark, resulting in minimal impacts on aquatic habitat. Construction would, however, be close to the water and could result in riparian vegetation being cleared to the water's edge and would still pose a potential risk of sediment transport and accidental spills into Mercer Slough.

Segment C

High-Value Habitat

With *Preferred Alternatives C11A* or *C9T*, and Alternative C9A with a connection to B2A there would be a relatively small area of temporary construction impacts on high-value wildlife habitat along Segment C. Segment C is in Downtown Bellevue, a highly developed area. Therefore, no wildlife habitat or wildlife displacement is expected with any of the other Segment C alternatives.

Wetlands and Wetland Buffers

Preferred Alternatives C11A and *C9T* would not impact wetlands. However, if connecting from Alternative B3, B3- 114th Design Option, or B7, there would be a potential temporary construction impact on the buffer to the Hilton Stormwater Pond (WR-16). This potential temporary impact would be primarily related to construction of the elevated guideway over Sturtevant Creek. Impacts on the pond buffer overlap with the impacts on the stream buffer.

All of the other Segment C alternatives connecting from Alternatives B3, B3- 114th Design Option, or B7 may have the same potential temporary construction impact on the buffer to the Hilton Stormwater Pond (WR-16) as discussed above for *Preferred Alternatives C11A* and *C9T*. In addition, Alternatives C9A and C14E may also have a potential temporary construction impact on the Hilton Stormwater Pond (WR-16) itself. The current design for Alternatives C9A and C14E shows a temporary impact on the portion of the pond at its outlet. For purposes of this EIS, it was assumed that the function of the entire 0.1-acre pond would be temporarily disturbed (see Table 4.8-7). Segment C alternatives that connect from Alternatives B2A or B2E would not affect WR-16.

Aquatic Habitat

Preferred Alternatives C11A and *C9T* connection with *Preferred Alternative B2M* would avoid Sturtevant Creek impacts south of Main Street, but relocating the creek for the Hospital Station east of I-405 would require relocating Sturtevant Creek channel just north of NE 8th Street (see Exhibit 4.8-6).

Preferred Alternatives C11A and *C9T* connecting from Alternatives B3, B3 - 114th Design Option, or B7 may result in sediment potentially reaching Sturtevant Creek behind the Hilton Hotel. Construction of support columns in the reach downstream of the I-405 culvert would be close to the channel, and vegetation may be cleared to the water's edge. Temporary construction impacts on riparian zone function would result as well. These construction activities would have a potential to cause sedimentation in Sturtevant Creek. However, careful implementation of BMPs along with the very low flows during the in-water work window would most likely result in a minimal and brief pulse of turbidity when flow is reconnected to the new channel. The route for both *Preferred Alternatives C11A* and *C9T* also crosses Sturtevant Creek just south of the NE 8th Street/ I-405 interchange, but the creek is in an existing pipe system at this location.

Alternatives C1T, C2T, C9A, and C14E would have the same impacts on Sturtevant Creek at the Hospital Station as described for *Preferred Alternatives C11A* and *C9T*. All Segment C alternatives, except Alternatives C1T and C7E, would have similar construction impacts on Sturtevant Creek as *C11A* and *C9T.*

Segment D

High-Value Habitat

Preferred Alternative D2A would affect approximately 1.9 to 2.1 acres of high-value wildlife habitat that would be directly affected during clearing for construction, depending on the connection option. The estimated area of high-value wildlife habitat that would be directly affected during clearing for construction along the other Segment D alternatives varies from approximately 0.2 to 0.3 acre (Alternative D3) to approximately 1.2 to 1.3 acres (Alternative D5). The proposed storage track with *Preferred Alternative D2A* would not affect high-value wildlife habitat.

Wetlands and Wetland Buffers

To construct *Preferred Alternative D2A*, elevated crossings over five wetlands (WR-7, WR-8SE, WR-11, WR-10W, and WR-15) and road construction related to the retained cut across 120th Avenue NE (WR-17) would result in potential temporary impacts on approximately 0.5 acre of wetland and approximately 1.7 acres of wetland/stream buffer. This alternative would have the largest temporary impact on wetlands and wetland/stream buffers compared to the other Segment D alternatives; however, the total impact would be relatively low. The potential temporary impacts on wetlands and wetland/stream buffers would be primarily related to staging and access necessary to construct the elevated guideway and would affect mostly Category 3 wetlands, a very small amount of one Category 2 forested wetland, and buffers that are currently disturbed by surrounding development, noxious weeds, stormwater from parking lots and buildings, and litter. Direct temporary construction impacts on wetland resources would be the same with either D2A design option, and would be the same as described above for *Preferred Alternative D2A*.

Alternative D3 would result in the smallest temporary impact on wetlands (0.1 acre) and wetland/stream buffers (0.1 to 0.2 acre, depending on the connection from the former BNSF Railway corridor versus NE 12th Street, respectively) compared to all the Segment D alternatives (see Table 4.8-7). This alternative would completely avoid all impacts on the wetlands east and west of 140th Avenue NE (WR-10E, WR-10W, and WR-11) and would have minor temporary impacts on wetlands WR-6, WR-8, and WR-15. In addition, connecting from Segment C via the former BNSF Railway corridor (rather than via NE 12th Street) would further avoid a small impact on the BNSF Matrix Wetland (WR-6).

The amount of temporary impact on wetlands and wetland/stream buffers from Alternatives D2E and D5 would be less than *Preferred Alternative D2A* but more than Alternative D3 (see Table 4.8-7). Alternative D5, which is also completely elevated, would have temporary impacts primarily on the West Tributary to Kelsey Creek Riparian Wetland Northwest (WR-8NW) and the wetland west of 140th Avenue NE (WR-11).

Aquatic Habitat

Construction of *Preferred Alternative D2A* would cross four streams (West Tributary to Kelsey Creek, Goff Creek, Unnamed Tributary to Kelsey Creek, and Valley Creek). While there is potential risk of sedimentation, the impacts are likely to be minimal as long as the appropriate BMPs to contain sediment are implemented. In-water work at the West Tributary to Kelsey creek would be isolated with a coffer dam or similar technique. In-water work in the Unnamed Tributary to Kelsey Creek would be isolated by bypass pumping during the connection phase of the culvert/pipe addition in 136th place NE.

All other Segment D alternatives cross streams. This could result in sediment potentially reaching the streams during construction. However, temporary construction impacts on salmonids are not expected because potential impacts that would occur in the West Tributary to Kelsey Creek, Goff Creek, and Unnamed Tributary to Kelsey Creek would be upstream from fish barriers in the streams and sediments would not likely be transported farther downstream to aquatic habitat that supports fisheries resources. Valley Creek would be crossed by an elevated span next to SR 520 by most alternatives and would have limited potential for sedimentation. Alternative D3 would require a culvert replacement at NE 20th Street. Careful implementation of BMPs should be adequate to minimize sedimentation there. Potential inadvertent spills could affect water quality and aquatic resources. Construction for stream crossings could also disturb western toads due to construction noise, interfering with their ability to hear mating or alarm calls.

Segment E

High-Value Habitat

Preferred Alternative E2 and E2 - Redmond Transit Center Design Option would affect approximately 1.5 acres of high-value wildlife habitat that would be directly affected during clearing for construction.

The estimated area of high-value habitat that would be directly affected during clearing for construction with the other Segment E alternatives varies from approximately 1.1 acres (Alterative E4) to approximately 2.1 acres (Alternative E1).

Wetlands and Wetland Buffers

Construction of *Preferred Alternative E2* would result in potential temporary impacts on 0.1 acre of wetland and on 0.9 acre of wetland/stream buffer. These impacts include a potential minor temporary disturbance (less than 0.1 acre of wetland and 0.4 acre of wetland buffer) to existing mitigation wetlands at SR 520 Bear Creek 1 and 2 mitigation sites at NE 76th Street. Constructing E2 - Redmond Transit Center Design Option would result in potential temporary impacts similar to *Preferred Alternative E2*. Potential temporary impacts on wetlands would be 0.2 acre, and 0.9 acre on wetland/stream buffer. Potential impacts on wetlands and wetland buffers from Alternatives E1 and E4 would be slightly less than those described for *Preferred Alternative E2*, as shown in Table 4.8-7.

Aquatic Habitat

Preferred Alternative E2 would cross the Sammamish River and Bear Creek, but no in-water work would be necessary at either crossing; therefore, no direct impacts on salmonid species would occur. Potential sedimentation from clearing and inadvertent spills could affect water quality and aquatic resources. Implementation of BMPs is expected to avoid sediment input and accidental spills. Construction noise near these streams could disrupt western toad reproduction by interfering with their ability to hear mating and alarm calls. The E2 - Redmond Transit Center Design Option would have potential impacts on aquatic habitat identical to those described for *Preferred Alternative E2*. Potential impacts on aquatic habitat from the other Segment E alternatives would be similar to *Preferred Alternative E2*, which would also cross the Sammamish River and Bear Creek.

Construction noise levels could displace wildlife from coniferous forest patches during construction along the Alternative E1 route. Additional minor displacement or disturbance may occur along *Preferred Alternative E2* where it borders Marymoor Park. Although no impacts are anticipated, all Segment E alternatives cross over Bear Creek, near a created wetland mitigation area (WR-12). If the *Preferred Alternative E2* alignment were shifted to accommodate other improvements in the former BNSF corridor, wetland impacts associated with crossing Bear Creek might change. Protective fencing would be installed to establish construction limits to avoid this area during construction.

All Segment E alternatives might affect wildlife at the Bear Creek Parkway crossing. Although specific bald eagle foraging locations are not known, construction of all Segment E alternatives across Bear Creek would cause temporary losses of forested stands and could temporarily displace any eagle foraging in the area.

Maintenance Facilities

Increased sediment inputs from construction of maintenance facilities in Segment D (MF1 and MF2) are not expected because the presence of beaver dams would detain and deposit sediment inputs. Construction of MF3 would require two culvert replacements in Goff Creek, which could result in temporary downstream sedimentation. No impacts are expected at the MF5 in Segment E.

4.8.4 Potential Mitigation Measures

Mitigation for ecosystem impacts is based on a hierarchy of avoiding, minimizing, and compensating for unavoidable adverse impacts. The design of the East Link Project incorporates avoidance and minimization techniques. Avoiding impacts on ecosystems is an important component of alternative development and design. Routes were developed based on numerous constructability issues, including the presence of sensitive areas. Where possible, sensitive areas were avoided, and when not possible, designs were modified to minimize impacts on ecosystems.

Sound Transit would meet all regulatory requirements and continue to implement proactive avoidance and minimization measures, as outlined in Appendix H3, related to BMPs and in adherence with federal, state, and local regulations. The Biological Assessment prepared for ESA consultation also identifies conservation measures and proposed aquatic habitat improvements that would become conditions of federal approvals for the project. Based on this analysis, and the mitigation measures proposed herein, the NMFS and the USFWS concurred on December 7, 2010, and February 23, 2011, respectively, that the determination of effect for ESA-listed species is “may affect, not likely to adversely affect.” The proposed determination of effect on Essential Fish Habitat under the Magnuson-Stevens Fishery Conservation and Management Act was “No Adverse Effect.”

4.8.4.1 Potential Mitigation for Operational Impacts

The following subsections describe mitigation for specific habitat types. Mitigation measures do not differ between the preferred alternatives and the other East Link alternatives.

High-Value Habitat

Project impacts on high-value wildlife habitats regulated by local agencies would be mitigated with habitat replacement or enhancement. The type of habitat to be established would depend on the affected species. The type of habitat to be replaced and mitigation ratios would be determined through discussions with federal, state, and local permitting agencies during final design and project permitting. Sound Transit would adhere to local ordinances regarding tree replacement ratios.

Wetlands and Wetland Buffers

The preferred alternatives for the proposed East Link Project would permanently affect approximately 0.7 acre of various wetlands and up to 2.5 acres with a combination of other alternatives. This relatively small amount of impact for an 18-mile-long project (a maximum of 0.14 acre of impact per mile of light rail) reflects Sound Transit’s commitment to avoid and minimize environmental impacts. Sound Transit has committed to achieving no net loss of wetland function and area on a project-wide basis. Sound Transit would apply the interagency wetland mitigation guidance prepared by Ecology, USACE, and USEPA (2006).

Compensatory mitigation sites would be identified within the same drainage basin and compensate for lost functions in-kind. The specific compensatory mitigation sites for unavoidable impacts on wetlands would be determined during final design and project permitting. Compensatory mitigation-to-impact ratios for replacement of wetlands would comply with the requirements of the local critical area ordinances (CAOs) and the interagency wetland mitigation guidance (Ecology et al., 2006). During field work, Sound Transit determined there are several opportunities for wetland mitigation within the study area close to potentially impacted areas that are expected to meet required mitigation ratios. Additional compensatory mitigation may be required for impacts on existing wetland mitigation sites and would be determined during final design and project permitting.

There are no existing approved mitigation banks in the Kelsey Creek subbasin. However, it is possible that a bank could become certified in the project study area in the future and could be used to mitigate project impacts.

Aquatic Habitat

On Sturtevant Creek at the Hospital Station where realignment of the stream channel would be required (for *Preferred Alternatives C11A, C9T,* and Alternatives C1T, C2T, C9A, or C14E), Sound Transit would reconstruct the new channel with natural stream habitat features. Riparian habitat functions would be improved with native riparian plantings. This reach is currently lacking shade. The newly shaded reach would help lower stream temperatures in the downstream reaches that support salmonids. Specific requirements and details of these measures would be established during final design and project permitting.

For Alternatives D3 or D5, which have culvert lengthening or shortening (Goff Creek and Valley Creek), habitat improvements might be made in the form of large woody debris placements. For maximum benefit to fisheries, habitat improvements could be done in either Goff Creek, Valley Creek, or West Tributary of Kelsey Creek below the anadromous fish barriers, wherever the best improvements and access exist. Along the West Tributary to Kelsey Creek, enhancement could include creating wider buffers for habitat and open space, environmental education, and stormwater management. Riparian plantings to mitigate impacts in riparian areas from shading by elevated tracks or bridges would be possible in a number of locations, such as in Mercer Slough, West Tributary to Kelsey Creek, Valley Creek, Bear Creek, and Sammamish River. The Sammamish River would receive the most benefit from this mitigation.

As mitigation for the increased culvert length on the Unnamed Tributary to Kelsey Creek (with *Preferred Alternative D2A* and Alternatives D3 and D2E), Sound Transit proposes to coordinate with the City of Bellevue to find and develop instream habitat improvements on Goff Creek in coordination with the City of Bellevue's larger plans to restore and daylight the creek.

4.8.4.2 Potential Mitigation for Construction Impacts

BMPs have been developed to avoid and minimize impacts during construction. These BMPs, listed in Appendix A of Appendix H3 and Section 4.9, Water Resources, involve implementation of conditions set forth in the HPA, WAC 220-110-070, for installing culverts during construction, Section 401 and Section 404 of the CWA, the NPDES permit, and the development of a Stormwater Pollution Prevention Plan (SWPPP) that prescribes implementation of measures for identifying, reducing, eliminating, or preventing sediment and erosion problems on site. The following subsections describe mitigation for specific habitat types for construction impacts by any of the East Link alternatives.

High-Value Habitat

Areas disturbed in the construction staging areas would be revegetated with native vegetation within one year following construction. Sound Transit would update its survey of bird nests during final design. If a bald eagle nest is found within one-half mile of the proposed construction limits, a bald eagle management plan would be prepared. Under the Migratory Bird Treaty Act (MBTA) nesting migratory bird nests cannot be destroyed during the breeding season. Sound Transit would consult with the USFWS on methods to implement during construction to avoid impacts on migratory birds consistent with the MBTA and the Bald and Golden Eagle Protection Act. Such methods would include not clearing vegetation in the Mercer Slough buffer during the nesting season for migratory birds.

Wetlands and Wetland Buffers

Wetlands and wetland/stream buffer areas disturbed by construction would be protected by BMPs and revegetated as soon as possible after construction. BMPs would be implemented to avoid construction impacts on wetlands and wetland buffers. Sound Transit would conduct detailed site surveys to establish existing topography and conduct hydrologic monitoring to restore topography. Restoration would include soil amendment and vegetation replacement.

Aquatic Habitat

BMPs would be implemented to avoid construction impacts on aquatic resources. Except for the in-water construction in Lake Washington, any in-water work would be isolated from adjacent waters using a coffer dam or other suitable technique. Such isolation is not necessary in Lake Washington due to the type of work done there (welding or bolting metal jackets together).

In-water work would be conducted during approved in-water construction windows. Where ESA-listed species may be present, stream crossings would not require in-water work and the project would not install infrastructure below the ordinary high water mark. Disturbed or temporarily cleared riparian vegetation would be replanted with suitable native species. The proposed channel relocation of Sturtevant Creek adjacent to the Hospital Station would follow guidelines found in the Integrated Streambank Protection Guidelines manual (WDFW, et al. 2002) and other current stream design documents.

If over-water construction takes place over Mercer Slough (with Alternative B7) or the Sammamish River (all Segment E alternatives) during the migratory period of ESA-protected species, nighttime lighting would be shielded from the waters below. Sound Transit would consult with the Tribes to avoid impacting Tribal fisheries from construction work in Lake Washington, from barge/boat transit through the Lake Washington ship canal, or through approaches to the Ballard Locks.

4.9 Water Resources

4.9.1 Introduction to Resources and Regulatory Requirements

This section describes the affected water resources and potential hydrologic, flooding, and water quality impacts associated with the East Link Project alternatives. The following laws, statutes, local ordinances, and guidelines address hydrology, water quality, and/or flooding issues:

- National Pollutant Discharge Elimination System (NPDES) Permit Regulations
- Presidential Executive Orders 11988 and 11990
- Washington State Water Quality Standards
- Washington State Department of Ecology (Ecology) *Stormwater Management Manual for Western Washington* (Ecology, 2005)
- WSDOT *Highway Runoff Manual* (WSDOT, 2008)
- Washington Department of Fish and Wildlife (WDFW) Hydraulic Project Approval (HPA) requirements
- The National Flood Insurance Protection Act
- The Flood Disaster Protection Act
- Sections 401, 402, and 404 of the Clean Water Act (CWA)
- Section 10 of the Rivers and Harbors Act
- City and County floodplain and drainage regulations
- City and County critical area ordinances
- City Shoreline Master Programs
- King County industrial rules and regulations
- King County Waste Discharge Permit for discharge of construction water to the sanitary sewer

A detailed discussion of wetlands, stream habitat, and stream/wetland buffers is in Section 4.8, Ecosystem Resources.

4.9.2 Affected Environment

The study area for water resources consists of the stream basins within which the project would be constructed (see Exhibit 4.9-1). The study area is located in Water Resources Inventory Area (WRIA) 8. Topography in the study area ranges from a high elevation of roughly 500 feet to Lake Washington at an elevation of 21 feet (King County, 2007a; City of Bellevue, 2007a; Horizon Systems Corporation [Horizon], 2007). Most of the basin areas crossed by the alternatives are urbanized, with impervious surface cover ranging from approximately 30 percent to a high of nearly 70 percent around Downtown Bellevue (City of Bellevue, 2002). Notable features in the study area include the heavily developed corridors of Interstate (I) 90, I-405, and State Route (SR 520); Seattle; Downtown Bellevue; Downtown Redmond; and surrounding suburban development. The affected environment is described in the following subsections that address surface waters, stormwater management, floodplains, wellhead protection zones (WPZs), and maintenance-facility surroundings. Project segments are addressed separately as applicable.

4.9.2.1 Surface Waters

Each of the water bodies in the study area is designated by Ecology for the following uses: core summer salmonid habitat; extraordinary primary contact recreation; domestic, industrial, and agricultural water supply; stock watering; wildlife habitat; harvesting; commerce and navigation; boating; and aesthetic values (WAC 173-201A-602). These uses are used to define the Ecology water quality standards that must be met for each water body.

Table 4.9-1 summarizes the parameters for Ecology's 303(d) water quality standards that have been exceeded within the water bodies in the study area. See the insert on this page for an explanation of 303(d) section of the Clean Water Act.

What is the Ecology 303(d) List?

The federal Clean Water Act (CWA), adopted in 1972, requires states to restore their waters to be "fishable and swimmable." The CWA established a process to identify and clean up polluted waters. Every 2 years, all states are required to prepare a list of water bodies that do not meet water quality standards.

Ecology has prepared a preliminary assessment of water quality in Washington. The assessed waters are listed in categories that describe the status of water quality. For those waters that are in the polluted category, beneficial uses—such as drinking, recreation, aquatic habitat, and industrial use—are impaired by pollution.

For 303(d)-listed water bodies, total maximum daily loads (TMDLs) are developed by Ecology for the pollutants that exceed water quality standards as a means for ultimately attaining the standards.

Segment A

Lake Washington is the dominant water resource in Segment A. It is the second largest natural lake in Washington and lies between Seattle and Bellevue, where it would be crossed by Segment A.

Washington State Department of Ecology (Ecology), 2008. 2008 Water Quality Assessment (303d List) available at: http://www.ecy.wa.gov/programs/wq/303d/2008/index.html

Most of the surface water in this segment drains to this lake, which is 1 to 3 miles wide and extends 18 miles from Renton to Kenmore. Its two largest tributaries are the Cedar and Sammamish Rivers; the Sammamish River lies within the study area and is discussed below. Lake Washington is a major recreational feature in the region, with heavy use for swimming, fishing, and boating. Although algae blooms can occur, the lake generally has good water clarity. Various locations throughout the lake have been placed on the 2008 Ecology 303(d) list of impaired water bodies for violations of standards for nitrogen, fecal coliforms, and total phosphorus (Table 4.9-1).

Segment B

In Segment B, Mercer Slough covers 1,330 acres and receives inflow from Kelsey Creek and Sturtevant Creek. The southern portion of the slough flows through the protected Mercer Slough Nature Park, underneath I-90, and into Lake Washington. In the northern part of the slough, Mercer Slough has an east and a west branch. Sturtevant and Kelsey Creeks flow into the northern portion of the slough, supplying flow to both branches. Both Mercer Slough and Kelsey Creek are within Bellevue's Shoreline Master Program. The gradient is gradual, which creates sluggish flow in these branches. Mercer Slough is at the same elevation as Lake Washington and has no perceptible flow. Approximately 35 percent of the basin area is covered by impervious surface, indicating a moderate level of basin development (City of Bellevue, 2002). The primary functions of Mercer Slough are to provide a migration corridor for salmon and trout and to support one of the largest wetlands within the area. The slough is used extensively for recreation, including nonmotorized boating. The water body is listed on the 2008 Ecology 303(d) list of impaired water bodies with violations of standards for temperature and fecal coliform (Table 4.9-1).

Segments C and D

Sturtevant Creek originates at Lake Bellevue near the Segment C and D boundary and drains southward from an area of just over 770 acres into Mercer Slough (City of Bellevue, 2002). Interstate 405 runs parallel to the creek, crossing it midway between Lake Bellevue and Mercer Slough. The creek is surrounded on both sides by heavy commercial and high traffic use, making the basin approximately 65 percent impervious. The entire basin falls within the City of Bellevue. Lake Bellevue, located in the upper portion of the basin, is completely surrounded by residential and commercial development.

Kelsey Creek drains an area of over 9,200 acres into Mercer Slough (Horizon, 2007). Smaller upstream tributaries include (from east to west) Sears Creek, Valley Creek, Goff Creek, and West Tributary Kelsey Creek. Kelsey Creek flows north through Larson Lake and loops around to the west and south, receiving the flows of the above-mentioned tributaries along the way.

Land use within the associated basins is primarily light to medium residential. An exception is the medium- to high- density commercial development along the southern portion of SR 520, which crosses Goff and Valley creeks. Directly to the west of the West Tributary Kelsey Creek headwaters is the SR 520 and I-405 interchange. These uses contribute to an overall impervious surface coverage of approximately 40 percent of the basin (City of Bellevue, 2002). The U.S. Geological Survey (USGS, 2007) has recorded flows within Kelsey Creek ranging from 2.4 to 412 cubic feet per second (cfs) near its confluence with Mercer Slough. The water body is also listed on the 2008 Ecology 303(d) list of impaired water bodies with violations of standards for temperature, fecal coliform, and dissolved oxygen (Table 4.9-1).

Segment E

In Segment E, the Sammamish River is the largest tributary flowing to Lake Washington, draining over

150,000 acres (Horizon, 2007). The river begins at the outlet from Lake Sammamish, then flows north and west for 15 miles through Redmond, Woodinville, Bothell, and Kenmore. Decades ago the river channel was dredged and straightened. Along its route, it collects flow from Bear Creek, Little Bear Creek, North Creek, and Swamp Creek. Land use within the Sammamish basin varies from urban commercial and residential to recreational, agricultural, and open space. Sammamish River and Bear Creek are within the City of Redmond's Shoreline Master Program.

Multiple subbasins of the Sammamish River watershed lie within the Segment E study area. The study area includes the first 2 miles of the Sammamish River as it flows through Marymoor Park, a large regional park, and past Downtown Redmond. Study area basins draining to the river include East and West Lake Sammamish, Westside, Marymoor, Bear Creek, and City Center (Exhibit 4.9-1). Flow records at a gage midway down the river measured flows ranging from 25 to 2,830 cfs. The Sammamish River has been added to Ecology's 2008 303(d) list of impaired water bodies in Washington because water quality in the river exceeds standards for temperature, fecal coliform, and dissolved oxygen (Table 4.9-1).

The headwaters of Bear Creek are located in southern Snohomish County. The creek drains a total of 31,000 acres and flows into the Sammamish River, just south of Downtown Redmond (Horizon, 2007). Major tributaries include tributary flows from Evans Creek, Cottage Lake Creek, and Seidel Creek. The lower portion of Bear Creek lies within the study area. Recorded flows along the lower portion of Bear Creek have ranged from 16 to 1,040 cfs (King County, 2007b). Bear Creek is on Ecology's 303(d) because it exceeds the allowable water quality standards for dissolved oxygen, fecal coliform, and temperature (Table 4.9-1). The Bear-Evans creek system is recognized as one of the top six natural resource basins in King County in the Waterways 2000 Program (King County, 2010).

4.9.2.2 Stormwater Management

Segment A lies entirely within the I-90 right-of–way. For much of the length of Segment A in Seattle, runoff flows to a combined pipe system that receives both stormwater runoff and sanitary sewage. This combined flow is conveyed to the West Point Treatment Plant, where the water is treated and discharged to Puget Sound. For the portion of I-90 crossing Mercer Island, the highway runoff is conveyed within the WSDOT-owned pipe system and discharged to Lake Washington. Some stormwater treatment is provided within vaults.

The remaining project segments lie within Bellevue and Redmond. These cities operate separated stormwater systems. These systems only collect and convey stormwater, not sanitary sewage. These systems typically discharge to the local streams. Urbanization within these cities has changed many of the land uses, from forested areas to urban development. Higher peak flows that are caused by impervious surface prevent infiltration from occurring and result in channel scour and degradation of stream habitat. To reduce the high flows that would otherwise occur within the streams, both cities operate a system of regional detention ponds. Runoff from developments constructed less than 15 to 20 years ago generally receives treatment and detention prior to discharging into the city stormwater systems. Each city operates a regional stormwater system within its downtown area. The regional system has the advantage of allowing new development to discharge stormwater to them without having to provide stormwater facilities for each new development. For convenience, these are referred to as the Bellevue or Redmond Stormwater Service Area in this EIS.

The cities in the study area have active stormwater management regulations and programs. Ecology provides guidelines for stormwater management in its *Stormwater Management Manual for Western Washington* (Ecology, 2005), also known as the Ecology Manual. Stormwater management design guidelines for Bellevue and Redmond are generally consistent with the Ecology manual.. The City of Seattle updated its stormwater code to more closely comply with the Ecology Manual in 2009.

4.9.2.3 Floodplains

Federal Emergency Management Agency (FEMA) 100-year floodplains, as mapped by FEMA, are shown in Exhibits 4.9-2 through 4.9-5. In general, 100-year floodplains that are crossed by the project are less than 200 feet wide; however, wider floodplains lie along the lower reaches of Bear Creek and along the Sammamish River. The Sammamish River valley is broad and gently sloping, with a 100-year floodplain that is nearly 1 mile wide in places.

Some of the smaller creeks and tributaries, including Goff Creek, Sears Creek, and Sturtevant Creek, do not have formally delineated floodplains. Occasional flooding has been reported on Sturtevant Creek south of Lake Bellevue and on Valley Creek north of the intersection of NE 20th Street and 140th Avenue NE (Watson, 2007).

Segment E
East Link Project

4.9.2.4 Groundwater

With the exception of Beaux Arts Village and the City of Redmond, which are the only cities in the study area that get their municipal water primarily from groundwater, there is limited use of groundwater in the study area. Groundwater levels vary considerably throughout the project vicinity. Glacial till underlies much of the area at shallow depth. Water infiltrates slowly through this material. It is not uncommon during the rainy season for perched groundwater to pond at the surface. During the drier summer months, groundwater plays a critical role in providing base flow to the streams in the area and recharging aquifers.

The Sammamish Valley supports a productive aquifer that is used by the City of Redmond as a source of drinking water from several municipal wells. The closest municipal well is less than a quarter mile away in Anderson Park, on the north side of SR 202. Thus, the area south of Downtown Redmond is designated as a WPZ (see Exhibit 4.9-5). Such areas serve as recharge areas surrounding domestic wells. The City of Redmond has a Wellhead Protection Ordinance (Chapter 13.07) that specifies measures to minimize the threat of groundwater contamination. Four zones are defined that require increasingly stringent controls and reporting of industrial and related activities that handle or store hazardous materials. This issue is discussed further in Section 4.9.3.2, Impacts During Operation, under the heading Groundwater.

4.9.2.5 Maintenance Facility Surroundings

Each of the maintenance facilities identified in the alternatives would be located in an area that is mostly impervious surface comprising office, commercial, warehouse, and light industrial facilities. Each area is generally well-served with stormwater infrastructure. There are no surface water bodies close to the 116th Maintenance Facility (MF1) or the SE Redmond Maintenance Facility (MF5). A wetland lies along the northern edge of the BNSF Maintenance Facility (MF2). Goff Creek flows through the western portion of the SR 520 Maintenance Facility (MF3). A portion of MF5 lies within the City of Redmond's WPZ 3. Redmond's WPZs are discussed in Section 4.9.2.4 above.

4.9.3 Environmental Impacts

As part of the conceptual engineering prepared for the East Link Project, a preliminary design was developed for the major stormwater detention and treatment facilities required for the proposed alternatives. In general, a conservative approach was taken when developing drainage concepts. Sound Transit applied the Western Washington Hydrology Model, developed by Ecology, to develop project hydrology and to determine facility sizing. Detention facilities were designed to achieve post-project stormwater flows equivalent to forested conditions, as required by Ecology. Further information on project stormwater can be found in Section 4.9.3.2, Impacts During Operation, under the heading Stormwater Treatment and Detention.

4.9.3.1 No Build Alternative

Under the No Build Alternative, some redevelopment and new development in the study area would still occur, with the potential to increase impervious surface and affect surface waters or groundwater flows, duration, and volumes.

Stormwater detention and treatment improvements would likely be delayed until future redevelopment occurs. Higher vehicle miles traveled is also expected under the No Build Alternative. This could result in more traffic, which can increase the amount of pollutants such as oils and heavy metals that, in turn, can degrade water quality.

As documented in Section 4.2, Land Use, a consequence of the No Build Alternative would be that a lower density of residential and commercial development would occur at key points along the proposed light rail corridor because the higher-density, transit-oriented development planned around light rail might not occur, or occur in less dense development patterns. By not building the East Link Project, some portion of this development would likely occur on the urban fringe rather than in the existing urban centers that would by served by the project. This type of development in less developed areas would result in an increase in impervious area and an associated increase in stormwater runoff in the urban fringe. Stormwater facilities associated with new development in the urban fringe area would reduce potential impacts on local streams; however, during the summer they could reduce stream flows, which could degrade water quality.

4.9.3.2 Impacts during Operation

Impacts of the build alternatives are presented by segment and address the following impacts on water resources: impervious area, stormwater treatment and detention, streams and floodplains, and groundwater.

Impervious Area

Impacts Common to All Build Alternatives

Overall, the project would increase the amount of existing impervious surface area by approximately 16 to 35 acres, approximately 14 to 24 percent (including a maintenance facility), depending on the alternatives selected. The route with the lowest increase in impervious surface area would result from the combination of *Preferred Interstate 90 Alternative (A1),* 112th SE Elevated Alternative (B2E), 106th NE Tunnel Alternative (C2T), NE 16th Elevated Alternative (D2E), and Redmond Way Alternative (E1), and MF3. The route with the greatest increase in impervious surface area would be *Preferred Alternative A1, Preferred 112th SE Modified Alternative (B2M), Preferred 108th NE At-Grade Alternative (C11A),* SR 520 Alternative (D5), and *Preferred Marymoor Alternative (E2)* (without the design option), and MF1.

Pollutant-Generating Impervious Surface

Impervious surfaces are considered a significant source of pollutants in stormwater runoff. Such surfaces include those which are subject to vehicular use; industrial activities (as defined in the Ecology Manual); and storage of erodible or leachable materials, wastes, or chemicals; and which receive direct rainfall or the run-on or blow-in of rainfall.

Impervious surfaces can increase stormwater runoff rates, volumes, and pollutant loads. These, in turn, can cause higher flows and degraded water quality in storm sewers and streams. Impervious surfaces can also result in decreased infiltration and aquifer recharge. New impervious areas from the project would include tracks and guideways, stations, park-and-ride lots, maintenance facilities, and roads. Ballasted (i.e., gravel) track sections were considered as impervious areas because of the high compaction and low permeability of the subsoils underlying the tracks.

Relocated roads to accommodate the project were also considered as project-associated impervious area because the new and replaced pavement would require stormwater treatment and detention. This includes surface roadways replaced after cut-and-cover tunnel construction. For those cases where elevated track would overlay a relocated road, the underlying impervious area of the road was not considered in the impervious area numbers (to avoid double-counting). Existing impervious area was obtained from a geographic information system (GIS) map of impervious areas developed in 2000 by King County (King County, 2004). This information was supplemented with aerial mapping conducted for the project. This represents the best impervious area data available for the study area.

Table 4.9-2 summarizes total existing and proposed impervious area within the project limits for each project alternative. The project limits include the right-of-way for the rail corridor, relocated streets, the maintenance facility, and new project park-and-ride lots. Appendix F4.9 provides a further breakdown by both project alternative and basin. In general, elevated alternatives would result in less new impervious area than at-grade alternatives because they would be typically narrower and relocate fewer roads. Alternatives with bored tunnels would also add smaller amounts of impervious area. However, tunnel alternatives with cut and cover construction, such as *Preferred 110th NE Tunnel Alternative (C9T)*, would result in more impervious surfaces.

Project pollutant-generating impervious surface (PGIS) comprises primarily roads parallel to the project route that would need to be reconstructed to accommodate the light rail tracks and road intersections with the at-grade rails. PGIS is also composed of access roads and parking areas at the project park-and-ride lots and the access roads, parking surfaces, and equipment maintenance and fuel and chemical transfer areas at the maintenance facilities. Project trackways, guideways, and stations are considered non-PGIS. Project trackways are only considered PGIS when combined with roadways, which carry pollutants from vehicular use. Since the portion *Preferred Alternative A1* east of the Mount Baker Tunnel (more than 5 miles) would be converted from high-capacity vehicle use to exclusive use by light rail, there would be a substantial decrease (about 35 acres) of PGIS for this segment. Other alternatives also convert portions of roadways that are now PGIS to exclusive light rail use. However, since these alternatives are near or comingled with automobile roadways, they are assumed to be PGIS for purposes of stormwater treatment.Some proposed project parking surfaces would contribute between 4 and 5 acres of PGIS unless the area is already PGIS, such as South Bellevue Park-and-Ride Lot or Overlake Transit Center. Elevated alternatives have little to no need for road reconstruction and, thus, would have relatively low PGIS values. For instance, the 112th NE Elevated (C7E) and the 110th NE Elevated (C8E) Alternatives have zero PGIS. In contrast, at-grade alternatives within urban settings (such as the Bellevue Way Alternative [B1], 112th SE At-Grade Alternative [B2A], *Preferred Alternative C11A*, 110th NE At-Grade Alternative [C9A], and NE 20th Alternative [D3]) frequently require relocating multiple lanes of roadway parallel to the alternative, which would result in a relatively large PGIS. Stormwater runoff from project-related PGIS would receive water quality treatment as discussed in the section below titled Stormwater Treatment and Detention.

TABLE 4.9-2
Existing and Proposed Impervious Areas by Project Build Alternative

[a] Range includes the variation in connections evaluated for the maintenance facilities.

[b] Includes reconstruction of existing roads.

[c] Approximate due to rounding.

[d] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts for either *Preferred Alternative C9T* or *B2M*.

[e] Impacts for D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

[f] Numbers in this row are derived from different combinations of segments in each column.

Segment A
Preferred Alternative A1 and the portion of Segment B within the Beaux Arts basin (see Exhibit 4.9-1) would be constructed completely within the existing I-90 corridor. There would be a limited amount of additional impervious area (0.6 acre, less than a 2 percent increase).

Segment B
Both variations of *Preferred Alternative B2M* add about 8.5 acres of new impervious area, the largest increase of the Segment B alternatives. *Preferred Alternative B2M* would increase impervious areas by 77 percent with the C9T connector and by 57 percent with the C11A connector.

The remaining Segment B alternatives would add between 3.7 and 6.2 acres of impervious area (a 29 percent to 36 percent increase in impervious area). Alternative B2E would add the least amount of impervious area.

Segment C
Preferred Alternatives C11A and *C9T* would add the most impervious area (4.9 acres, a 21 percent and 33 percent increase, respectively) of the Segment C alternatives, primarily along 112th Avenue NE.

Other Segment C alternatives would result in a 6 percent to 38 percent increase in impervious area. New impervious area added by these alternatives would range from a low of 0.5 acre with Bellevue Way Tunnel Alternative (C1T) and Alternative C2T, to a high of 4.7 acres with Alternative C9A.

Segment D
Preferred NE 16th At-Grade Alternative (D2A) would add between 10.3 and 10.7 acres of impervious area, depending upon the design option selected, which would increase impervious area by approximately 36 percent to 41 percent.

Alternative D5 would result in the largest increase in new impervious area (12.5 acres, a 147 percent increase) of all the Segment D alternatives because it would be routed through the largely less developed portion of the corridor immediately south of SR 520. Alternatives D2E and D3 would result in 8.9 acres and 9.8 acres of new impervious area. Alternatives D2E and D3 would result in a 61 percent and 33 percent increase in impervious area, respectively.

Segment E
*Preferred Alternative E2*and E2 - Redmond Transit Center Station Design Option would add 4.4 to 5.8 acres of impervious area (a 26 percent to 32 percent increase), which is the largest increase in impervious area of the Segment E alternatives. Alternative E1 would have the smallest impervious area increase in Segment E (4.2 acres, a 25 percent increase).

Maintenance Facilities
The MF1 and MF5 would result in a local increase in impervious area. Because of the highly developed nature of the areas proposed for the MF2 and MF3, selecting either facility would result in a net local decrease in impervious area. This is because these two maintenance facilities would result in more landscaped, pervious area than currently exists in the respective areas. Impervious surfaces at maintenance facilities would be PGIS except for sidewalks, roofs, and tracks that are not crossed by motor vehicles.

Stormwater Treatment and Detention

In general, stormwater management would meet the requirements of the Ecology Manual. Within WSDOT right-of-way, the requirements of the *Highway Runoff Manual* (WSDOT, 2008) would be met, which is equivalent to Ecology's manual. In addition, local jurisdiction requirements for stormwater management would be met.

Stormwater Detention
The temporary storage of stormwater runoff and subsequent release at a slower rate.

Stormwater Treatment
Stormwater ponds and underground vaults are used to remove sediments and pollutants from stormwater. They collect sediments on the bottom of the pond or vault, where maintenance workers can clean them out on a regular basis.

Total Suspended Solids
Organic and inorganic particles that are entrained within and carried by water. The particles are typically sand, silt, and clay, but may include pebbles and larger rocks in fast-flowing water.

Runoff from PGIS areas would require basic water quality treatment. In accordance with the Ecology Manual, Sound Transit would provide enhanced stormwater treatment for all roadways where the average daily traffic volume exceeds 7,500 vehicles per day. Enhanced stormwater treatment would be provided for runoff from any new and replaced pavement on these high traffic volume streets.

The guideways and stations have no motor vehicle traffic or other sources of pollution-generating activities and are therefore classified as non-PGIS, except where at-grade track crosses intersections. No stormwater treatment facilities would be required in these areas.

Certain water bodies have been designated by Ecology as exempt from requiring detention, including Lake Washington, Mercer Slough, Lake Sammamish, and the Sammamish River. Prior to discharge from the project site, stormwater detention to predevelopment (i.e., forested) levels would be provided for project runoff flowing to the remaining (nonexempt) water bodies, which includes the other study area water bodies except for Sturtevant Creek. Sturtevant Creek lies within a basin designated an urban basin by the City of Bellevue. As a result, project runoff within this basin need only be detained so as to maintain existing peak flows. Non-PGIS runoff would be conveyed separately from PGIS runoff because it does not require water quality treatment. Where practical, runoff would be dispersed over pervious areas from elevated guideways where infiltration could occur. The East Link Project conceptual design for major stormwater facilities, including stormwater ponds and underground vaults, can be found in Appendix G1. As shown in Appendices F4.9 and G1, stormwater detention and treatment facilities (on-site systems such as vaults or ponds) have been sized for the project alternatives. However, in some basins, an alternative approach is to contribute to regional detention or treatment facilities where allowed by the local jurisdiction.

Most of the East Link Project lies within highly urbanized areas, with limited undeveloped area available for surface detention. As a result, most of the stormwater facilities would be within underground vaults. Project runoff in the Downtown Redmond Stormwater Service Area would require neither project-related detention nor treatment facilities because it would be within the Redmond Stormwater Service Area. Project runoff in the Downtown Bellevue Stormwater Service Area in Segments C would only require project-related treatment facilities for the PGIS areas. The stormwater facilities provided by the project would meet the requirements of the local jurisdictions. As a result, stormwater impacts from the project would not be significant. (Appendix F4.9 presents a tabular summary of the project stormwater facilities and compares the alternatives.)

For *Preferred Alternative D2A*, a storage track is planned in the former BNSF Railway corridor, with office space, storage, and parking for vehicle operators. The only anticipated work would be light cleaning of the interiors of the trains. No wastewater would be discharged into the surrounding storm facilities.

With *Preferred Alternative E2,* WSDOT is proposing to reconfigure an Ecology embankment (also referred to as a media filter drain) that borders Marymoor Park and treats runoff from SR 520. Sound Transit proposes reconstructing the highway shoulder and moving the Ecology embankment from the shoulder to the highway median. Stormwater treatment would be provided using a dual filter drain (BMP RT.07.2 of the *Highway Runoff Manual,* WSDOT, 2008). This approach would meet the highway requirements while also providing the required treatment of highway runoff using less land area.

Sound Transit's Environmental and Sustainability Management System encourages innovative measures to reduce stormwater runoff, such as low-impact development or other on-site measures, to be incorporated into the project where feasible. Some opportunities exist for runoff to be dispersed to adjacent natural areas. Other measures could include, but are not limited to, the following and will be considered during detailed design:

- Flow dispersal of runoff from at-grade trackways where they lie adjacent to Mercer Slough in Segment B
- Permanent landscaping of areas above tunnel segments in Segment C following construction
- Drip-dispersion of runoff from elevated guideway along portions of SR 520 that remain landscaped in Segment D

The proposed maintenance facility is categorized as an industrial facility. In addition to motor vehicle traffic, petroleum products and other chemicals would be stored and used at the site, and there would be other maintenance activities as well. Therefore, to meet the requirements of the Ecology Manual, a strategy of enhanced stormwater treatment would be implemented at the maintenance facility. A constructed stormwater wetland would provide the enhanced stormwater treatment for the maintenance facility. On-site stormwater detention would also be provided.

Surface Water and Floodplain Impacts

Impacts Common to All Alternatives

As discussed in Section 4.8, Ecosystem Resources, considerable effort was made during development of the alternatives to avoid critical areas, including streams and lakes, because changes to water bodies can have substantial adverse impacts on aquatic ecosystems, floodplains, and real estate property. This section discusses water features that would be unavoidably impacted by the project.

Floodplains and floodways are subject to federal and local regulations. A floodplain is defined as the area adjacent to a stream or river that is inundated during the 100-year flood event. The floodway is the stream channel and adjacent portions of the floodplain that must be reserved in order to discharge the base flood elevation (100-year flood) without increasing the water surface elevation more than 1 foot. The City of Redmond generally prohibits floodway encroachment unless mitigating measures achieve zero rise in the floodway, or base flood elevations increase less than 1 foot and significant environmental impacts are mitigated (Ordinance 2259). The City of Bellevue prohibits construction that results in any rise of the base flood; an exception is construction using post-and-piling techniques, which is presumed without modeling to cause no rise in the base flood (Ordinance 5680). Fill within the 100-year floodplain must be mitigated by excavating an equal volume of material from within a proximate portion of the FEMA floodplain and at a comparable elevation to create "compensatory storage."

The East Link Project would generally employ elevated guideways to cross water bodies at a number of locations (Exhibits 4.9-1 through 4.9-5). The exact location of columns to support the elevated guideway would be determined during design, but columns would be located outside the stream channel floodway or floodplain when it is possible to span these areas. In general, an elevated guideway crossing of a stream, floodplain, or floodway would cause little or no impact. Impacts on specific streams are discussed below.

Segment A
No impacts on streams, floodplains, or floodways would occur within Segment A.

Segment B
Preferred Alternative B2M is located outside of the Mercer Slough floodplain and, therefore, would result in no adverse impact.

Alternative B7 would cross approximately 415 feet of the Mercer Slough floodplain just north of I-90. A minimum of two columns would be located in the floodplain but not within a waterway channel. Compensatory storage requirements would be minor with no adverse impact. Alternative B3 - 114th Extension Design Option and BNSF Alternative (B7) would cross Sturtevant Creek north of SE 2nd Street on an elevated structure and would not impact the creek. There would be no impacts with the other Segment B alternatives.

Segment C
With *Preferred Alternatives C11A* or *C9T,* Sturtevant Creek would be relocated from the east to the west side of the former BNSF Railway corridor to route the channel around the proposed Hospital Station. This would require installing a new culvert under the NE 8th Street right-of-way and the abandonment of the existing culvert. The new stream would convey the 100-year flow as defined by the City of Bellevue. These two alternatives also cross Sturtevant Creek just south of the NE 8th Street/ I-405 interchange. The creek is in a pipe at this location. A bridge column would be placed in the location where the creek pipe makes a sharp turn. The pipe would be relocated to avoid the bridge column and to allow for future interchange improvements by WSDOT.

Preferred Alternatives C11A or *C9T* connecting to Alternative B3 or Alternative B7 follow Sturtevant Creek for approximately 500 feet and 700 feet, respectively, where Sturtevant Creek first parallels 114th Avenue NE (see Exhibit 4.9-3). The alternatives are elevated through this reach on supporting columns, and supporting columns would be located in the creek's riparian buffer zone, thus avoiding the creek channel. In addition, because a FEMA flood insurance rate map has not been developed for this section of creek, the 100-year floodplain would need to be determined through modeling during final design. The upstream area draining to the creek is of modest size, approximately 400 acres. High flows in the creek would be limited, and the 100-year floodplain would likely be narrow. As stated above, the project design would avoid placing support columns for the elevated guideway in the channel or its streambanks, thereby avoiding disturbance of the creek and minimizing impacts on the floodplain.

The Sturtevant Creek impact near Lake Bellevue for *Preferred Alternatives C11A* or *C9T* would also occur under Alternatives C1T, C2T, C9A, or C14E.

The Sturtevant Creek riparian impact described above for *Preferred Alternatives C11A* and *C9T* would also occur for the other Segment C alternatives that connect from Alternatives B3 and B7, i.e., all Segment C alternatives except C1T.

Segment D
With the exception of *Preferred Alternative D2A* (discussed below), the Segment D alternatives and design options would have no permanent impact on the floodplains or floodways. However, there would be project crossings at several tributaries of Kelsey Creek—West Tributary, Goff, Valley, and Sears Creeks. These are shown in Figure 4.9-4 and Table 4.9-3 and are discussed in this section.

Preferred Alternative D2A crosses four streams in Segment D. It is routed along a portion of the West Tributary of Kelsey Creek. Four columns are proposed within a large impoundment of the stream that serves as a regional detention pond. The pond is greater than 100 feet wide at this point; therefore, the impact of the

TABLE 4.9-3
Segment D Stream Crossings by Alternative

Stream	*Preferred Alternative D2A*	Alternative D2E	Alternative D3	Alternative D5
West Tributary of Kelsey Creek	Elevated crossing with 4 columns placed within a stream impoundment	Elevated crossing	Elevated crossing	Elevated crossing
Goff Creek	Crosses at an existing piped stream that would not be disturbed[a]	Elevated crossing at an existing stream culvert	Crosses at an existing piped stream that would not be disturbed[a]	Elevated crossing
Unnamed Tributary to Kelsey Creek	Portion of stream would be enclosed in a longer pipe	Portion of stream would be enclosed in a longer pipe	Portion of stream would be enclosed in a longer pipe	None
Valley Creek	Elevated crossing	Elevated crossing	Existing culvert would be replaced with a bridge	Elevated crossing
Sears Creek	None	None	Crosses at an existing stream culvert that would not be disturbed	None

[a] A box culvert would be constructed under the alternative to support future city plans to daylight Goff Creek.

columns on the flood storage and conveyance capacity of the creek would be negligible.

Preferred Alternative D2A crosses Goff Creek at NE 16th Street where the stream is currently conveyed in a pipe. It is not anticipated that this pipe would be disturbed during project construction. However, a box culvert would be constructed allowing for the eventual daylighting of Goff Creek as planned by the City of Bellevue. *Preferred Alternative D2A* crosses Valley Creek on an elevated structure over the SR 520 culvert, and it would not affect Sears Creek.

Preferred Alternative D2A would affect a 130-foot-long open channel and a 0.2-mile piped segment of the Unnamed Tributary to Kelsey Creek (see Exhibit 4.9-4). This stream reach carries local runoff and is conveyed through a series of culverts and ditches along 136th Place NE. Most, if not all, of the flow of the creek is routed through a 24-inch-diameter storm drain pipe at 136th Avenue NE and NE 16th Street. *Preferred Alternative D2A* would require widening 136th Place NE. The road passes through a highly commercialized area, and widening the road would eliminate the ditches, thereby enclosing the entire stream in a pipe through this section. The long-term water quality and flow impacts would not be affected by this change. As indicated in Table 4.9-3, Alternative D2E would have elevated crossings at three streams. There would be no stream impacts at three of these crossings. Due to column placement, a portion of the Unnamed Tributary to Kelsey Creek would need to be piped. Alternatives D2E and D3 would impact the same 130 feet of open channel and 0.2-mile piped segment of the Unnamed Tributary to Kelsey Creek along 136th Place NE, as described for *Preferred Alternative D2A*.

Alternative D3 would cross five streams. Alternative D3 would be in a retained cut where it crosses Valley and Sears Creeks. The Sears Creek culvert is approximately 12 feet below the retained cut and would not be affected. The Valley Creek culvert at NE 20th Street is a 6-foot-diameter metal culvert with between about 1 and 1.5 feet of cover. If Alternative D3 is selected, then the existing culvert would need to be replaced with a fish-passable bridge extending 30 feet downstream of the existing culvert outlet, as shown in Exhibit 4.9-4, Inset B. Like D2E, Alternative D3 would result in the piping of a portion of an unnamed tributary to Kelsey Creek.

Alternative D5 would have elevated crossings at three streams and would therefore have no stream impacts.

Segment E

Preferred Alternative E2 would cross the Sammamish River north of Marymoor Park. This alternative would be elevated at the crossing location (see Exhibit 4.9-5), where the floodway is about 235 feet wide and the floodplain is about 3,050 feet wide. At least one column would be located in the floodway, but flooding impacts would be negligible.

Compared to the other Segment E alternatives, the largest amount of fill placed within a floodplain would be required for *Preferred Alternative E2*, where a 1,000-foot-long, at-grade segment in the floodplain adjacent to SR 520 would displace approximately 650 cubic yards of soil below the 100-year water surface elevation. The average depth of fill below the 100-year water elevation would be less than 0.5 foot. *Preferred Alternative E2* would include compensatory storage as required to offset the impacts of any fill placed within floodplains.

Compensatory storage could consider enhancing Marymoor Park through grading, or areas along the Sammamish River north of SR 520.

Preferred Alternative E2 would cross Bear Creek along the route of the former BNSF Railway corridor, located about 250 feet downstream from NE Redmond Way. The existing former BNSF Railway bridge opening creates a channel constriction. Flood modeling performed for the creek (Parametrix, 2007) indicates that the 100-year flood elevation upstream from the bridge is 39.6 feet, approximately 1.5 feet higher than downstream from the bridge. *Preferred Alternative E2* would span Bear Creek on a bridge extending for a distance of about 100 feet on either side of the center of the 30-foot bridge opening. The existing embankment for the former BNSF railroad would be widened to about 50 feet to accommodate both retained fill for the track and a 15-foot-wide parallel strip for a bicycle path (to be constructed by others). The old railroad bridge structure would remain in place, and the geometry of the stream channel would not be changed. The lowest portion of the proposed light rail bridge would be at least 3 feet above the 100-year flood elevation of Bear Creek. The potential future shift in the *Preferred Alternative E2* alignment to accommodate the City of Redmond's utility project and the regional trail could change the position of the crossing over Bear Creek but is unlikely to change the relation to the flood elevation.

The fill placed along the railroad embankment would displace approximately 150 cubic yards of floodplain storage. Compensatory storage would be provided near the edge of the floodplain near the rail crossing. The existing stream opening would remain unaltered. Two culverts about 60 feet south of the bridge would remain as they are. If disturbed during guideway construction, these culverts would be replaced at their existing locations and elevations. In summary, the new project bridge would not permanently impact Bear Creek. The existing stream opening would remain unaltered. Although the height of the existing railroad embankment would be raised by the retained fill, this would not affect the flow conditions through the bridge because the embankment lies above the 100-year water surface elevation and is not overtopped during flood conditions. The flow conditions and flood water surface elevations near the bridge would remain unchanged.

Alternative E1 and the Leary Way Alternative (E4) would also cross Sammamish River and Bear Creek at similar locations as *Preferred Alternative E2* and would therefore have the similar impacts.

Similar to *Preferred Alternative E2*, Alternatives E1 and E4 would cross the Sammamish River north of Marymoor Park. Both alternatives would be elevated at their crossing locations (see Exhibit 4.9-5). Where the two alternatives cross the Sammamish River, the floodway width is about 600 feet (for Alternative E1) and 200 feet (for Alternative E4). Similar to *Preferred Alternative E2*, under either Alternatives E1 or E4, at least one column would be located in the floodway, but flooding impacts would be negligible.

Alternative E1 would have an elevated crossing over Bear Creek along the route of the inactive, former BNSF Railway bridge. Constructing columns on this embankment would minimally impact the floodplain and would not change the existing Bear Creek channel. Similar to *Preferred Alternative E2*, Alternative E4 would span Bear Creek on a bridge. Impacts on Bear Creek from Alternatives E1 and E4 would be similar to those described above for *Preferred Alternative E2*.

Maintenance Facilities

MF3 would be constructed at an existing business park through which Goff Creek flows, as shown in Exhibit 4.9-4 (see Inset A). The west side of MF3 would extend over the creek. Sound Transit would consider two approaches in final design to accommodate the creek that could potentially improve Goff Creek. In the first approach, the creek would remain in its present location, and two short, fish-passable bridges would be constructed under the rail loop on the western end of MF3 to accommodate the creek. A 50-foot-wide riparian buffer would be established on each side of the creek. In the second approach, the stream would be relocated around the west side of MF3, which would increase the length of the stream by about 220 feet.

The Bel-Red Corridor Study identifies redevelopment opportunities for this area (City of Bellevue, 2007b). The riparian buffer mentioned above would be compatible with redevelopment plans identified in the Bel-Red Corridor.

MF2- borders a wetland. The wetland buffers discussed in Section 4.8.3 (Ecosystem Resources) would provide adequate protection against water quality impacts. No other water bodies would be impacted by the other maintenance facilities.

Groundwater

The project could impact groundwater in a number of ways. Adding impervious surface could reduce the amount of infiltration into the soil and reduce groundwater recharge. Reduced groundwater recharge could also result in reductions in the base flows of streams in the project area. Overall, the project would increase the amount of existing impervious surface area by approximately 16 to 35 acres, depending on the alternatives selected. Because of the highly linear nature of the project, this impact would occur across many miles of project path, the groundwater level would not likely substantially decline, and other serious groundwater impacts are not anticipated.

Additionally, interrupting groundwater flows may result in adverse impacts by changing the amount of water that eventually reaches the surface and the location where groundwater surfaces. There are three areas where this project may affect groundwater: (1) in retained-cut areas along *Preferred Alternative B2M*, (2) at the tunnels under Downtown Bellevue in Segment C and (3) in Redmond. These potential impacts are discussed below.

Retained Cut

Portions of *Preferred Alternative B2M* would be constructed in retained cuts along Bellevue Way SE. Without mitigation, the concrete-lined retain cuts could intercept and re-direct local groundwater flow, with potential impacts on down-gradient wetlands and surface water features. Mitigation for this potential impact is discussed in Section 4.9.4.2 below.

Tunnel Seepage

Several alternatives in Segment C involve constructing tunnels under Downtown Bellevue. When constructing tunnels, a drainpipe would be installed to convey groundwater that might seep into the tunnel. The tunnel design criteria for the Central Link Project (the previously constructed Pine Street Stub tunnel) stipulated no greater than 0.2 gallon per minute per 250 feet of tunnel. When similar criteria are applied to the four Bellevue tunnel alternatives (*C9T*, C1T, C2T, or C3T), they are estimated to collect between 6 to 7 gallons per minute (gpm) of tunnel seepage. The seepage rate for the tunnel would be tightly controlled using the same techniques as used for the Central Link Project. These small flows would flow into a storm drain system and be discharged outside of the tunnel to the local stormwater system. This would not be expected to substantially affect the groundwater level in the central Bellevue area.

Redmond Wellhead Protection Zone

As stated in Section 4.9.2.4, the City of Redmond identifies four WPZs. Zones 3, 2, and 1, respectively, lie in increasing proximity to the City's municipal wells and, therefore, have increasingly stringent requirements to protect the underlying aquifer from contaminants that might be introduced as a result of land use activities, Zone 1 being the most stringent. All Segment E alternatives would cross through all four WPZs. As shown in Exhibit 4.9-5, the proposed route and station alternatives in Downtown Redmond would lie within Zones 1 and 2. There would be no vehicle maintenance nor storage or use of hazardous materials associated with the light rail tracks and the stations. Project runoff would be directed to the existing regional stormwater management system for treatment and discharge to the Sammamish River. The project would, therefore, result in no additional impact on the area's groundwater.

South of Bear Creek, the SE Redmond Park-and-Ride Lot and the MF5 would lie within Zone 3. There would be vehicle maintenance work, and some fuels and hazardous materials would be stored at the maintenance facility. The soils in this area are permeable. Runoff from these project facilities would be collected, treated, and infiltrated on site, as is the current practice within this area. The Redmond City Code (WPZ Performance Standards) lists the requirements for stormwater management for developments within Zone 3. Applicable provisions that would be incorporated into project design to protect groundwater quality include the following:

- Containment and treatment of runoff from vehicle fueling, maintenance, and storage areas
- Secondary containment for hazardous materials unloading and storage areas
- Stormwater best management practices (BMPs) approved by the City's Technical Committee

These measures would protect groundwater quality. Standard stormwater BMPs would be required for WPZ4 and would be implemented as discussed below in Section 4.9.3.3.

Best Management Practices

BMPs are activities, construction measures, maintenance procedures, and structural and/or managerial practices, that when used singly or in combination, prevent or reduce the release of pollutants and other adverse impacts to surface and groundwater.

4.9.3.3 Impacts during Construction

Impacts Common to All Build Alternatives

The potential water quality impacts resulting from construction activities would be increased turbidity and sedimentation in the receiving streams as a result of stormwater runoff from disturbed construction sites. Erosion and sedimentation typically occur when rainfall and stormwater runoff erode soil and deposit the eroded materials downslope or downstream from the construction area. Erosion and sedimentation can result from a variety of potential actions associated with construction, including the following:

- Removing vegetation that exposes soil to erosion
- Exposing soil by way of grading, filling, and excavation
- Tracking soils onto roads by vehicles
- Constructing in or near wetlands, lakes, streams, or drainage courses
- Constructing slopes that collect and concentrate stormwater, causing erosion
- Dewatering excavations such as pier foundations, trenches and tunnels

The runoff from newly poured concrete surfaces can have a high pH (parts hydrogen), often above pH 9, which can result in degraded water quality and is lethal to fish. In addition, total suspended solids from the concrete fines might result in a milky-white appearance of the runoff, exceeding turbidity requirements. Both of these issues were encountered during Central Link Project construction.

Because the total amount of ground disturbance during construction would be more than 1 acre, an NPDES general construction stormwater permit would be required for this project. One of the permit requirements is a project-specific stormwater pollution prevention plan (SWPPP). The SWPPP would be developed and implemented in accordance with the Sound Transit Environmental and Sustainability Management System. This plan would include a temporary erosion and sediment control plan (TESC), a hazardous materials management plan, and would employ BMPs during construction to minimize the potential for soil erosion and sedimentation and to protect water quality. Potential BMPs include the following:

- Minimizing the amount of cleared area at a construction site
- Stabilizing construction entrances and haul roads using quarry spalls
- Washing truck tires at construction entrances, as necessary
- Constructing silt fences downslope from exposed soil
- Protecting catch basins from sediment
- Containing and controlling concrete and hazardous materials on site.
- Installing temporary ditches to route runoff around or through construction sites, with periodic straw bales or rock check dams to slow and settle runoff
- Providing temporary plastic or mulch to cover soil stockpiles and exposed soil
- Using straw wattles to reduce the length of unbroken slopes and minimize runoff concentration
- Using temporary erosion control blankets or mulch on exposed steep slopes to minimize erosion before vegetation is established
- Constructing temporary sedimentation ponds to remove solids from concentrated runoff and dewatering before being discharged
- Conducting vehicle fueling and maintenance activities no closer than 100 feet from a water body or ditch

A TESC plan also would include a water quality monitoring plan and a schedule for inspecting the erosion control measures for effectiveness. Water from dewatering, such as from tunnels or guideway pier construction, would be treated as required to meet discharge requirements identified on the SWPPP or hauled off site for proper disposal. Pavement slurry and residue from road cutting and grinding would be collected and properly disposed of off site, and a concrete containment and disposal plan would also be prepared. An Ecology-certified erosion and sediment control lead (CESCL) would be employed to conduct the inspections, and deficiencies would be promptly corrected. These measures would minimize the likelihood for serious water quality problems occurring during construction.

The concrete used for the project would need several months to cure enough so that the pH decreases to acceptable levels. Stormwater runoff would be tested, and if excessive levels of pH or turbidity are found, then the water quality of the runoff would be treated before it is released to storm sewers or a receiving water body. If discharge of treated construction or process water to a sanitary sewer is proposed, approval must be obtained from the King County Industrial Waste Division and the local jurisdiction.

For construction within and over streams or other water bodies, a Hydraulic Project Approval (HPA) would be required. The HPA would be obtained from WDFW before work begins. The project would comply with the HPA's stream protection measures, including diverting stream flow around the construction area and limiting the construction period to the required "work window," a period of the year identified in the HPA when fish would be minimally affected.

Segment A

Preferred Alternative A1 would be constructed within the I-90 corridor. Nearly all construction would occur within the existing roadbed of I-90 and would, therefore, not be expected to pose a substantial erosion risk.

Preferred Alternative A1 would cross over a large area that is designated as an erosion-hazard area in Mercer Island. Clearing, grading, and other construction-related activities in areas with steep slopes or unstable soils has the potential to cause severe erosion problems. No further construction impacts would be anticipated.

Segment B

Preferred Alternative B2M involves construction activity adjacent to Mercer Slough, including constructing a retained cut structure near the Winters House. This poses a sedimentation hazard to the slough. However, the BMPs listed in the previous subsection would provide adequate protection against water quality degradation.

Alternative B7 would be constructed over Mercer Slough. In addition to measures listed above, construction inside Mercer Slough Nature Park and over the slough waterway would include building a stilt and plank temporary roadway to reduce compressing the soils and limiting construction material into and adjacent to Mercer Slough. Dewatering water from pier excavations would be either treated prior to release to remove suspended solids or hauled off site for proper disposal.

Similar measures would also be used to minimize the impact of the elevated portion of the 112th SE Bypass Alternative (B3) that would traverse a large wetland south of SE 6th Street.

Alternative B7 would cross a steep area that is more than 1 mile long, located along the east side of Mercer Slough and west of I-405. However, this portion of the alternative would be constructed within a railroad bed where only minor grading and minimal hillside disturbance would occur.

The other Segment B alternatives that follow Bellevue Way SE would have similar impacts as those described for *Preferred Alternative B2M*.

Segment C

Groundwater seepage from tunnel boring activities for *Preferred Alternative C9T* could be up to 250 gpm; this is typical of other projects with deep underground parking structures or foundations that have recently been constructed in Downtown Bellevue. The existing storm drainage system has adequate capacity to accept this quantity of pumped groundwater. Prior to discharge, the collected groundwater would be treated to meet city discharge requirements before it is discharged into the storm drainage system.

The other Segment C alternatives would have similar impacts as those described above for *Preferred Alternatives C11A* and *C9T*. Groundwater impacts due to seepage from tunnel boring activities for Alternative C2T or 108th NE Tunnel Alternative (C3T) would be similar to those discussed above for *Preferred Alternative C9T*.

Any of the Segment C alternatives that connect from Alternative B3, B3 - 114th Design Option, or Alternative B7 would involve constructing four guideway columns close to Sturtevant Creek channel, north of SE 6th Street. The stream could experience substantial siltation during construction. BMPs discussed earlier in this section would reduce the potential for this impact. An HPA would be required and obtained from the WDFW. Stream protection measures are further discussed in Section 4.8, Ecosystems Resources, and would provide adequate protection of water quality in Sturtevant Creek during construction.

Segment D

Preferred Alternative D2A would construct several columns within the impounded section of the West Tributary of Kelsey Creek. The stilt and plank temporary roadway and proper treatment/disposal of pier excavation water discussed in Segment B would also be carried out at this location. No further construction impacts would be anticipated with *Preferred Alternative D2A* or the D2A design options.

Alternative D3 would require the reconstruction and extension of the Valley Creek culvert under NE 20th Street. Temporary creek relocation and related stream protection measures specified in an HPA obtained for this crossing would ensure that creek water quality was adequately protected. There would be no impacts related to Alternatives D2E or D5.

Segment E

Preferred Alternative E2 includes construction activity along the SR 520 corridor as well as construction activity related to the Sammamish River and Bear Creek crossings. Construction stormwater BMPs and measures stipulated in the HPAs for these stream crossings would be implemented to reduce impacts on these two watercourses.

The other Segment E alternatives would have similar impacts as those described above for *Preferred Alternative E2*.

Maintenance Facilities

The BMPs presented previously under Impacts Common to All Build Alternatives would generally apply to the construction of the maintenance facility. A wetland lies on the north side of the MF2, and Goff Creek flows through the west side of the MF3. Construction could impact these water bodies. Potential impacts would be minimized by implementing BMPs, adhering to the HPA requirements for relocating Goff Creek, and adhering to the buffer recommendations in Section 4.8.3.

4.9.4 Potential Mitigation Measures

A number of regulatory requirements for addressing water resource impacts would be part of the project design, as discussed in Section 4.9.3. Where the project alternatives would result in adverse impacts after the application of minimization measures included in the project design, further mitigation would be necessary as described below.

During final design, opportunities for regional management of project stormwater and on-site control of stormwater runoff would be explored. The project design team would work with local jurisdictions to identify opportunities to incorporate low-impact development features into the project, including consideration of runoff dispersion, permeable pavement, green roofs, and other measures to retain rainfall on site and minimize project runoff. Stormwater management and treatment principles of Low-Impact Development (LID) will be favored over “traditional” stormwater treatment and applied wherever feasible.

For *Preferred Alternative B2M*, the sealed, concrete-lined retained cut constructed near Mercer Slough would prevent groundwater from entering the retained cut but allow groundwater to flow down-gradient beneath the cut. This would maintain the existing groundwater flow toward the Slough and sustain down-gradient wetlands and other surface water features.

If any of the Segment C alternatives that connect from Alternatives B3 or B7 were to be selected, then the elevated guideway columns would be placed outside of the Sturtevant Creek stream channel, avoiding direct impact on the creek. For *Preferred Alternative D2A*, the Unnamed Tributary to Kelsey Creek would be relocated into a new 24-inch-wide storm drain. The stream would remain in the existing storm drain until a new storm drain is constructed. Rerouting the tributary would occur within the permitted work window during the summer when flows in the stream do not typically exist or are extremely low. If Alternative D3 were to be selected, then the existing shallow culvert crossing of NE 20th Street by Valley Creek would be replaced with a bridge that is structurally capable of supporting the light rail crossing at this location. Bridge construction would meet applicable fish passage criteria.

If the MF3 were to be selected, then Goff Creek could be relocated several hundred feet to the west to avoid the facility. Alternatively, the stream could be restored in its present location and the culverts replaced by ones that allow fish passage and migration. The stream would be relocated and restored in a manner compatible with the Bel-Red Corridor redevelopment plans.

4.10 Energy Impacts

4.10.1 Introduction to Resources and Regulatory Requirements

Project construction activities and operating vehicles, commuter trains, and light rail in the East Link Project study area would consume large amounts of energy. This section estimates the amount of energy that would be consumed during project construction and the amount of energy that would be consumed by vehicles operating within the study area.

The study area for this analysis is the Puget Sound Regional Council (PSRC) four-county region, which includes King, Pierce, Snohomish, and Kitsap Counties; this is the same study area used for the traffic data analysis. Some general discussion of statewide energy use and potential energy impacts on local utilities is also included.

Federal and state agencies regulate energy consumption through various policies and programs. Federal guidelines such as the Energy Policy and Conservation Act of 1975 and the Energy Independence and Security Act of 2007 require minimum fuels consumption efficiency standards for new automobiles sold in the United States. The Corporate Average Fuel Economy Program was created to help manufacturers adhere to the efficiency standards. The Safe, Accountable, Flexible, and Efficient Transportation Act: A Legacy for Users (SAFETEA-LU), which was passed in 2005, promotes the reduction of traffic congestion to improve safety, and protect air quality and the environment (Federal Highway Administration [FHWA], 2007).

4.10.2 Affected Environment

This section discusses the existing energy use characteristics at both the state level and in the study area. Detailed information about energy use at the project level is not available; as a result, Sound Transit used the state-level and utility service area trends to help determine energy consumption at the local level.

According to the Energy Information Administration (EIA), Washington consumed over 2,050 trillion British thermal units (Btu) of energy in 2008, which is the energy equivalent of approximately 354 million barrels of oil. In 2008, Washington's per capita energy consumption was approximately 312 million Btu, which is the energy equivalent of approximately 2,500 gallons of gasoline per person per year (EIA, 2010).

In recent years, the increasing popularity of pick-up trucks, vans, and sport utility vehicles has reduced new vehicle fuel efficiency. Although Washington's economy is becoming less energy-intensive because of improved technology and productivity increases, the state's overall energy consumption is expected to grow due to growth in population, jobs, and demand for vehicle travel. If petroleum prices remain high, then growth in energy consumption might moderate as consumers purchase more fuel-efficient vehicles and change travel patterns (Washington State Department of Community, Trade, and Economic Development [CTED], 2007).

The study area's electricity needs are currently served by two utilities: Seattle City Light, a municipal electric utility serving the City of Seattle, and Puget Sound Energy, an investor-owned utility that provides electricity and natural gas to communities throughout western Washington. Table 4.10-1 lists the number of customer and generation capacity for each utility's service area.

TABLE 4.10-1
Utility Data

Utility Data	Seattle City Light	Puget Sound Energy
Number of customers, 2009	394,731	1,075,400
Total generation (MWh), 2009	13,714,000	25,971,000
Btu equivalent	46.8 trillion	88.6 trillion

Source: Seattle City Light, 2010a; Puget Sound Energy, 2010a.
Notes:
1 MWh = 3,412,141 Btu.
Total generation includes generated power and purchased power.

BTU	British thermal unit
MWh	megawatt hour

Both utilities rely on their own generation sources as well as energy purchases through long- and short-term contracts with other energy producers (i.e., Bonneville Power Administration). In 2009, Seattle City Light produced approximately 43 percent of its own power and purchased the other 57 percent; Puget Sound Energy produced approximately 46 percent of its own power and purchased the other 54 percent (Puget Sound Energy, 2010a; Seattle City Light, 2010a) Of the total power generated in 2009 (including own generation and purchased power), hydroelectric generation accounted for approximately 91 percent of Seattle City Light's power (Seattle City Light, 2010b) and approximately 28 percent of Puget Sound Energy's power (Puget Sound Energy, 2010b).

Today, the project vicinity is congested during the peak traffic periods. Excessive idling and stop-and-go traffic conditions substantially reduce fuel economy compared with free-flow conditions. Exhibit 4.10-1 shows the average miles per gallon (mpg) for vehicles traveling at speeds between 15 and 75 miles per hour (mph). As shown on the graph, fuel efficiency is greatest when vehicles are traveling between 45 and 55 mph. Because of current conditions in the project vicinity, there are often times throughout the day when the study area is congested and vehicles are operating at inefficient speeds.

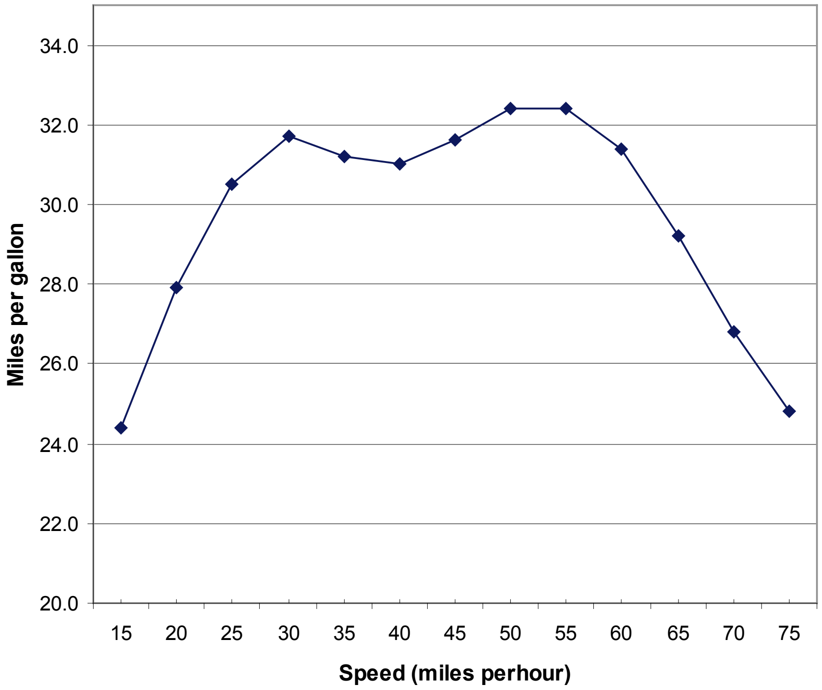

EXHIBIT 4.10-1
Average Fuel Consumption Rates for Automobiles

Table 4.10-2 presents the most recently available daily vehicle miles traveled (VMT) and energy consumption by mode for the PSRC four-county region. The PSRC model did not reflect ridership for Sound Transit Central Link because it was not operational until 2009. Ridership for the Sound Transit Central Link is approximately 6,300 VMT per day.

According to the PSRC traffic model and the Sound Transit ridership model, the existing daily VMT for the region is approximately 71.8 million. The daily energy use by the different transportation modes is approximately 484,000 million Btu.

TABLE 4.10-2
Existing Daily Vehicle Miles Traveled and Energy Consumption (2005)

Vehicle Type	Consumption Factor	Existing Conditions[a]	
		Daily VMT	MMBtu
Passenger vehicle	5,894	68,181,645	401,865
Heavy duty	22,077	3,391,855	74,882

4.10.3 Environmental Impacts

4.10.3.1 Impact Estimating Methodology

The energy analysis evaluated operational and construction energy use by the project and the demand on regional energy supply. Sound Transit estimated long-term (operational) impacts from the VMT estimates by mode presented in the PSRC four-county traffic forecast model. The PSRC four-county region total VMT estimates for light rail were modeled based on the projected *Sound Transit 2: A Mass Transit Guide, The Regional Transit System Plan for Central Puget Sound* (ST2). The four-county regional VMT was separated into passenger miles and heavy truck miles to account for differences in energy consumption levels. Passenger vehicles' VMT, which includes light-duty trucks, was assumed to contribute 95 percent, and heavy trucks contribute the remaining 5 percent of the total regional VMT. All energy consumed was converted to Btu to provide a common measure among the energy sources.

The Btu for each VMT category was obtained from the *Transportation Energy Data Book, Edition 29* (U.S. Department of Energy [DOE], 2010). The energy consumption factor for passenger vehicles includes the weighted average for cars, motorcycles, and light trucks. Energy consumption factors by mode are as follows:

- One passenger vehicle mile (includes cars, motorcycles, and light trucks) = 5,894 Btu
- One heavy-duty vehicle (trucks) mile= 22,077 Btu
- One transit bus mile = 39,906 Btu
- One light and heavy rail mile = 62,601 Btu
- One commuter rail mile = 94,587 Btu

During project construction, energy would be consumed when construction materials are produced and then when transported to the site. Operating and maintaining construction equipment would also consume resources. Construction-related impacts were estimated by applying a highway construction energy factor to the total construction cost of the East Link Project. The California Department of Transportation (CALTRANS) derived energy consumption factors for different light rail transit facilities in *Energy and Transportation Systems*, and these factors are still widely used in the industry today (CALTRANS, 1983). For this analysis, the following energy consumption factors were used to estimate the energy consumed during project construction:

- Track work: 5,044 Btu per 2007 dollars
- Structures: 5,044 Btu per 2007 dollars
- Electric substations: 7,752 Btu per 2007 dollars
- Signaling: 2,122 Btu per 2007 dollars
- Stations, stops, and terminals: 5,044 Btu per 2007 dollars
- Parking: 6,203 Btu per 2007 dollars
- Maintenance facilities: 5,044 to 6,203 Btu per 2007 dollars

The consumption factors were reported in Btu per dollars of construction spending. Because the CALTRANS report was developed using 1973 construction dollars, the energy consumption factors had to be adjusted to account for the change in construction costs. The California Construction Cost Index was used to adjust the factors to 2007 dollars.

4.10.3.2 No Build Alternative

Under the No Build Alternative, the daily VMT for the PSRC four-county region would increase from approximately 71.8 million VMT in 2005 to approximately 116.7 million VMT in 2030. As shown in Table 4.10-3, this daily VMT would be slightly higher than the VMT with the East Link Project. Vehicles operating in the study area would consume approximately 778,000 million Btu of energy in 2030. The No Build Alternative would place additional demands on energy in the region as a result of increased passenger trips, greater levels of congestion, and slower speeds when compared with the build alternatives. However, the potential demand on the electric utilities that the East Link light rail system would place on the electric grid would not occur.

The No Build Alternative also involves no construction activities related to the light rail system; therefore, no additional energy would be consumed because of construction activities under the No Build Alternative.

4.10.3.3 Impacts During Operation

The long-term direct energy impacts analysis of the East Link Project are based on projected 2030 regional traffic volumes and daily VMT consistent with PSRC data and the transit modeling performed by Sound Transit. Sound Transit combined one alternative from each segment to develop a "representative project" from Seattle to Redmond. The representative project consisted of the following segments: *Preferred Interstate 90 Alternative (A1)*, 112th SE Bypass Alternative (B3), Couplet Alternative (C4A), *Preferred NE 116th At-Grade Alternative (D2A)*, and *Preferred Marymoor Alternative (E2)*. The passenger vehicles' VMT was then modified to reflect a high- and low-ridership level to provide a high and low range of operational impacts.

The representative project route contains different Segment B and C routes than the *Preferred Alternative*, but the traffic volumes and daily VMT that were developed using the representative project would be similar to the volumes modeled using the segments that make up the *Preferred Alternative*. Therefore, the energy consumption when operating the *Preferred Alternative* is expected to be similar to the energy impacts of the representative project presented below.

TABLE 4.10-3
Daily Vehicle Miles Traveled and Energy Consumed

Vehicle Type	Consumption Factor (Btu per mile)	2030 No Build		2030 Build: High Ridership		2030 Build: Low Ridership	
		Daily VMT	MMBtu	Daily VMT	MMBtu	Daily VMT	MMBtu
Passenger vehicle	5,894	111,389,000	656,531	111,159,647	655,179	111,212,303	655,489
Heavy duty	22,077	5,085,486	112,272	5,084,386	112,248	5,084,386	112,248
Transit bus	39,906	201,916	8,058	199,056	7,944	199,056	7,944
Commuter rail	94,587	1,524	144	1,524	144	1,524	144
Light rail	62,601	12,241	766	16,600	1,039	16,600	1,039
Total		116,690,167	777,771	116,461,213	776,554	116,513,869	776,864

Btu British thermal unit
MMBtu million British thermal unit
VMT vehicle miles traveled

Table 4.10-3 presents the VMT, energy consumption rate (Btu per mile), and total energy consumption for each mode and the high- and low-ridership build scenario. When compared to the No Build Alternative, each build scenario would result in a reduction of passenger and transit bus vehicle miles as people shift their demand to the light rail system. Overall, energy use during project operation in the PSRC four-county region is expected to result in approximately 0.1 to 0.2 percent less energy than the No Build Alternative. Compared with the No Build Alternative, similar energy savings would be expected with the *Preferred Alternative* as with the representative project.

Operating the light rail system would place a demand on the local electricity utilities, Seattle City Light and Puget Sound Energy. The light rail system is estimated to use 1,039 million Btu per day, or approximately 304 megawatt hours (MWh) per day. Assuming that the light rail system would operate 365 days per year, the annual light rail system energy consumption would be approximately 110,000 MWh.

This represents approximately 0.3 percent of the total 2009 generation for Seattle City Light and Puget Sound Energy combined. Operating the light rail system is not expected to have a substantial impact on the electric utilities**.**

Sound Transit adopted a Sustainability Initiative in 2007 that promotes energy efficiency, minimizes waste, and implements more energy-efficient alternatives than current practices.

According to the initiative, Sound Transit will integrate efficient operating practices at existing and new facilities, use energy-saving equipment to reduce energy demand, and maximize intermodal transit connections to reduce automobile VMT. Many of these practices have been incorporated in the Central Link initial segment. Implementing these and other sustainability initiatives will also reduce energy consumption with East Link operation.

4.10.3.4 Impacts During Construction

The amount of energy used during construction of a project is roughly proportional to the project cost. To analyze short-term energy impacts, Sound Transit estimated the amount of energy that would be consumed during construction by applying the CALTRANS construction energy consumption factor to the project construction costs. Only direct construction costs related to this project were used to calculate energy consumption during the construction period. Thus, professional engineering and right-of-way costs were removed from the analysis.

The analysis compared the total energy consumptions for the two *Preferred Alternative* scenarios and the overall low- and high-cost project scenarios (described in the list below). The segment alternatives for each alternative scenario are as follows:

- ***Preferred Alternative* (High-Cost).** This project consists of *Preferred Alternative A1*, *Preferred 112th SE Modified Alternative (B2M)*, *Preferred 110th NE Tunnel Alternative (C9T)*, *Preferred Alternative D2A*, and *Preferred Alternative E2* with E2 - Redmond Transit Center Station Design Option.
- ***Preferred Alternative* (Low-Cost)**. This project consists of *Preferred Alternative A1, Preferred Alternative B2M, Preferred 108th NE At-Grade Alternative (C11A), Preferred Alternative D2A*, and *Preferred Alternative E2* with E2 - Redmond Transit Center Design Option.
- **Low-Cost Project**. This project consists of *Preferred Alternative A1,* 112th SE At-Grade Alternative (B2A), 112th NE Elevated Alternative (C7E), SR 520 Alternative (D5), and *Preferred Alternative E2* with E2 - Redmond Transit Center Design Option.
- **High-Cost Project**. This project consists of the *Preferred Alternative A1,* Bellevue Way Alternative (B1), Bellevue Way Tunnel Alternative (C1T), NE 20th Alternative (D3) and *Preferred Alternative E2* with E2 - Redmond Transit Center Design Option.

Table 4.10-4 lists the energy consumed during construction for each *Preferred Alternative* scenario and the low- and high-cost scenarios. The energy consumption information presented below provides a possible range of energy consumption during construction. The estimated energy consumption for the preferred alternative (low- and high-cost) scenarios would total 7.5 trillion Btu and 8.4 trillion Btu, respectively. The *Preferred Alternative* (high-cost) scenario with *Preferred Alternative C9T* would likely consume approximately 12 percent more energy than the *Preferred Alternative* (low- cost) scenario with *Preferred Alternative C11A*. Respectively, the low-cost and high-cost alignment would consume approximately 8 percent less and 32 percent more energy than the low-cost *Preferred Alternative*. As mentioned previously, no additional energy would be consumed because of construction activities with the No Build Alternative.

Because the project could be phased due to funding availability, interim termini were developed that would end the project at or east of the Ashwood/Hospital Station located in Segment C. The impact of a phased approach would be to delay some of the energy consumption related to construction and possibly delay the operational savings anticipated from the project until the full line is completed.

The maintenance facility was not included in the project energy analysis because it would operate as a project to support the larger Link system. A preferred maintenance facility will be determined through future operations analysis and site in the future and may or may not include the maintenance facility sites studied in this Final EIS. The maintenance facilities do not vary in their conceptual design and elements, and therefore, a representative energy use is projected to be approximately 501,000 million British thermal units (MMbtus). The maintenance facility would include buildings, which based on Sound Transit's sustainability objectives, would be built in accordance with Leadership in Energy and Environmental Design (LEED) principles.

Sound Transit's commitment to sustainability practices includes conserving energy during construction. Sound Transit would work with the contractor on measures that might include, but not be limited to, conserving fuel usage and extracting recyclable materials before demolition.

4.10.4 Potential Mitigation Measures

Operating the light rail system is expected to consume less energy than the No Build Alternative and is not expected to overburden the electric utilities' power availability; therefore, no mitigation would be required.

4.11 Geology and Soils

4.11.1 Introduction to Resources and Regulatory Requirements

Geology and soil considerations important to the East Link Project include topography, geology, soil characteristics, groundwater conditions, and geologic hazards. These considerations affect the type of construction methods used for the project and, if not adequately considered during project design, could affect the long-term operations and safety of the light rail system.

Washington State's Growth Management Act (GMA) (Revised Code of Washington [RCW] Chapter 36.70A) requires all cities and counties to identify critical areas within their jurisdictions and to formulate development regulations for their protection. Among the critical areas designated by the GMA are Geologically Hazardous Areas, which are areas susceptible to erosion, sliding, earthquakes, or other geologic events. These hazards could affect the design, construction, and operation of the project and, if not considered appropriately, could pose a risk to public safety.

Geology and soil considerations are closely related to groundwater conditions. While this section includes general information on groundwater within segments, more detailed information about groundwater along the alternative routes is discussed in Section 4.9, Water Resources. Locations of possible contaminated soils and contaminated groundwater are identified and discussed in Section 4.12, Hazardous Materials.

4.11.2 Affected Environment

Geologic units and soil characteristics along each alternative were assessed within the study area to establish the affected environment for geology and soils. The study area for specific issues related to geology and soils is defined as the area within approximately 100 feet on either side of each alternative and their associated facilities. However, when assessing the geology and soil characteristics, it was also necessary to consider geology on a regional basis to understand the mechanism leading to current geology. The need for a regional review is particularly important to seismicity because the source of this hazard could originate tens to hundreds of miles from the project routes.

Sound Transit assessed geologic units and soil characteristics using maps—including topographic maps, surficial soils maps, geologic maps, and geologic hazard maps—published by governmental agencies, including the U.S. Department of Agriculture (USDA) and U.S. Geological Survey (USGS). Sound Transit also assessed available site-specific geotechnical information for each alternative based on geotechnical explorations conducted as part of other projects along the alternative routes. The exploration information includes data from over 500 soil borings that were drilled within the study area between 1948 and 2010 (Exhibit F4.11-7 in Appendix F4.11). As part of conceptual and preliminary engineering for the East Link Project, 114 additional borings were drilled between 2007 and 2010 to augment available subsurface soil and groundwater information in Segments A, B, C, and D (Jacobs, 2007; CH2M HILL, 2011*)*. Information from these project-specific explorations was included in the development of the affected environment description for the study area.

4.11.2.1 Topography, Regional Geology, and Seismicity

The East Link Project is located in the central portion of the Puget Sound Basin, an elongated, north-south trending depression situated in western Washington between the Olympic Mountain Range to the west and the Cascade Mountain Range to the east. The regional topography consists of a series of north-south trending ridges separated by deep troughs. The troughs are now occupied by streams, lakes, and waterways, including Puget Sound, Elliott Bay, Lake Washington, and Lake Sammamish. Land elevations range from about 15 to 380 feet (North American Vertical Datum of 1988) across the East Link Project corridor (Exhibit 4.11-1).

This regional topography was shaped mainly by glaciations that moved back and forth across the region over 10,000 years ago. The glaciers were sometimes several thousand feet thick. Soils that were over-ridden by glaciers are generally very hard or compact as a result of the weight of the glaciers. More recently, erosional processes and landform changes made by human development of the area have modified the regional topography.

Geology in the region generally includes recently developed surficial soils (created within the last 10,000 years) over a thick sequence of glacially consolidated soils and then bedrock. Appendix F4.11 shows the surficial geology of the area (see Exhibits F4.11-1 through F4.11-4) and provides descriptions for each of the geologic units and a summary of their engineering properties (Table F4.11-1). Bedrock along the route is generally located more than 500 feet below the ground surface.

Exhibit 4.11-1

Project Location and Topography

East Link Project

The region is seismically active—the project vicinity has been subject to earthquakes in the historical past and will undoubtedly experience earthquakes again in the future. Earthquakes in the Puget Sound region result from any one of three sources: the Cascadia subduction zone off the coast of Washington, the deep intraslab subduction zone located approximately 20 to 40 miles below the Puget Sound area, or shallow crustal faults. The closest active crustal source is the Seattle Fault Zone. The southern portion of the project is mapped within the Seattle Fault Zone. The northern terminus of the light rail project in Redmond is located within 6.5 miles of the Seattle Fault Zone (USGS, 2007) (as shown in Exhibit 4.11-1).

4.11.2.2 Geologic Hazards

An important consideration for the construction and operation of the East Link Project would be the potential for geologic hazards, including steep slopes, erosion, landslides, seismicity, and soft soils. Geologic hazards from seismicity include ground-shaking, fault movement, and secondary seismic impacts such as liquefaction and liquefaction-induced settlement. Table 4.11-1 identifies the type of geologic hazard areas within or adjacent to each segment. Areas with hazards from liquefaction, steep-slopes, landslides, and peat deposits, are shown in Appendix F4.11, Exhibits F4.11-5 and -6. The geologic hazard potential identified in Table 4.11-1 was established based on Washington state and local regulatory requirements involving steep slopes, erosion, landslides, seismic hazards, and soft soils. The geologic hazard potentials are defined as follows:

- Steep slope hazards are areas where slopes are steeper than 15 to 40 percent. These areas are considered hazards because they are prone to slope failure, either during periods of wet weather or during large seismic events.
- Erosion hazards occur where soils may experience severe to very severe erosion from construction activities. Certain types of soils with fine particles, such as silts, are more prone to erosion from wind and water. The potential for erosion also increases as the slope steepness increases. Surficial soils and topographic maps can be used to identify areas that are particularly susceptible to erosion.
- Landslide hazard areas are mapped where there is evidence of past landslides, where the slope is 15 percent to 40 percent and the soils are underlain by silt or clay that can perch groundwater, or where the slope is steeper than 40 percent, regardless of soil type. This type of hazard is closely associated with the steep slope hazard. A landslide can vary in size from a small, surficial slump to a large, multi-acre occurrence.

Geology and Soils Definitions

Cascadia subduction zone is the place where the Juan de Fuca and North American lithospheric plates (the crust and the uppermost mantle of the earth) come together, with the Juan de Fuca sliding below the North American Plate.

Groundwater is water that is found beneath the earth's surface. The top of the groundwater is referred to as the water table. The water table location can change with the season.

Intraslab subduction zone is the zone between the earth's crustal plates. This zone is the source of large earthquakes below Puget Sound.

Liquefaction is a loss of strength in loose sands and non-plastic (i.e., with little or no cohesion) silts located below the water table.

Lateral spreading is the lateral movement of near-level or sloping ground associated with liquefaction of soil during an earthquake.

Surface faulting is displacement of the land surface by movement along the fault.

Tsunami is a sea wave resulting from an underwater landslide or seafloor movement during an earthquake.

Seiches are periodic oscillations in an enclosed body of water during an earthquake.

TABLE 4.11-1
Potential Geologic Hazards within or Adjacent to Each Segment

Geologic Hazard Potential	Segment				
	A	B	C	D	E
Steep slopes (more than 40 percent)	✓	✓	✓	✓	✓
Erosion	✓	✓	✓	✓	✓
Landslide	✓	✓			✓
Seismic (distance from Seattle Fault Zone)	0 to 2 miles	0 to 2 miles	2 to 3.5 miles	3.5 to 5 miles	5 to 6.5 miles
Liquefaction potential	Moderate to high	Moderate to high	Low to moderate	Low to moderate	Low to moderate
Soft soils (including peat settlement)	✓	✓	✓	✓	✓

- Seismic hazard areas are subject to potential risk from earthquake-induced ground-shaking and fault displacement. The ground-shaking can result in slope failure, settlement, soil liquefaction, a tsunami, or a seiche—all of which pose a risk to the public.
- Liquefaction is of particular concern because it has often been the cause of damage to structures during past earthquakes. Liquefaction occurs where soils are primarily loose and granular in consistency and located below the water table. The consequences of liquefaction include loss in the strength and settlement of the soil. The loss of strength can result in lateral spreading, bearing failures, or flotation of buried vaults and pipes.
- Examples of liquefiable soils located in the study area include:
  - Some artificial fill
  - Tideflat deposits
  - Mass wastage deposits
  - Lake deposits
  - Recessional outwash deposits
- A tsunami or a seiche is a possible secondary impact from a seismic event. Both mechanisms involve water waves that can be created by an earthquake. In general, the East Link alternatives are located either too far from Elliott Bay and Lake Sammamish or too high above Lake Washington for tsunami or seiche inundation to be a concern.
- Soft soil conditions can also be a form of geologic hazard. Peats and soft clays are common soils that result in geologic hazards. These soils have low strengths and are compressible. Without appropriate design consideration, soft soil can lead to embankment failures during construction or long-term settlement and would add to the maintenance requirements for the project.

4.11.2.3 Site Geology

This section summarizes geotechnical characteristics and groundwater conditions for each segment of the study area based on existing geologic maps and geotechnical boring logs. Table F4.11-1 in Appendix F4.11 provides a summary of general geologic unit descriptions. More detailed discussions of the soils and geologic units, as well as groundwater conditions along the segment routes, are provided in geotechnical reports prepared for conceptual and preliminary engineering (Jacobs, 2007; CH2M HILL, 2011).

Segment A

The construction of Interstate 90 (I-90) and adjacent land development has modified the terrain within Segment A, changing the original topography and sometimes altering the type of exposed soil or the depth to groundwater.

The geotechnical characteristics of soils in this segment range from loose sands, which could be unstable if they were to liquefy, to glacially consolidated sands and gravels, which generally provide good bearing support and little settlement.

The groundwater elevation varies along the Segment A alternative.

- Groundwater in the Rainier Valley was typically found at around 20 feet deep and was not encountered in many borings on the hillsides.
- Artesian groundwater conditions were encountered at depths of approximately 30 to 60 feet below the ground surface on the east side of Baker Ridge at the west approach to the I-90 floating bridge. Artesian conditions occur when groundwater is at a greater pressure than the water depth at which groundwater is encountered because a low-permeability soil layer prevents the groundwater from flowing upward.
- Groundwater near each shore of Mercer Island was encountered at the lake level, while groundwater within the center of Mercer Island was approximately 20 feet below the ground surface.

Segment B

Much of the land along the Segment B corridor has been developed with residential and light commercial structures for retail uses. The Mercer Slough Nature Park, which is a large wetland between Bellevue Way SE and I-405, remains relatively undeveloped.

Soil conditions change significantly within Segment B, depending on the proximity of the location to Mercer Slough Nature Park:

- Within the Mercer Slough Nature Park, soft clays and peats are found. These soils are often low in strength and prone to settlement. WSDOT has found the thickness of the soft soil to be in excess of 100 feet at the center of the slough. In addition to being soft and settlement prone, WSDOT also reports that these soils move horizontally as the level of Lake Washington changes, resulting in large soil loading to the existing I-90 structures that cross the slough.

- Away from Mercer Slough, such as along Bellevue Way SE and 112th Avenue SE and along the former BNSF Railway corridor, glacially consolidated soils are found close to the ground surface. These soils are very strong and resistant to settlement, making them very stable during construction and long-term operations.

Steep slopes are present in areas along the west side of Bellevue Way SE and along the east side of the former BNSF Railway corridor.

Groundwater depth varies with topography and the season.

- Kelsey Creek, to the northeast of Mercer Slough, has a shallow unconfined aquifer, which primarily discharges into Mercer Slough.
- Within the Mercer Slough wetlands, groundwater is at or near the ground surface. It also is present and highly pressurized (artesian) in a sand unit at approximately 100 to 125 feet below the ground surface.
- In upland areas on either side of the Mercer Slough, groundwater is often encountered within 10 to 30 feet of the ground surface.

Segment C

Development in Segment C varies from homes, apartments, hotels, and relatively low-rise commercial buildings in the south to Downtown Bellevue, which is dominated by highrise buildings and an extensive amount of underground development for parking garages, building foundations, and utilities. Most of the land in Segment C has been modified by human development.

Soils consist of fill, underlain by deposits of glacial till composed of silt, sand, and gravel.

- The fill is usually less than 15 feet in thickness and is the result of the extensive construction that has taken place in the area. Fill areas along 112th Avenue SE and in the Downtown Bellevue core are highly variable in terms of soil type and consistency. The variability of this fill makes it less dependable for construction, and it can be prone to settlement and/or liquefaction.
- The till below the fill is generally very compact and stable, thus providing good bearing support and posing limited risk of settlement, which makes these soils suitable for constructing and operating various light-rail alternatives, including tunnel options.

Segment C includes alternatives that would involve tunneling through Downtown Bellevue. Geotechnical characteristics and groundwater conditions along potential tunnel alternatives within Segment C are described in Table 4.11-2. This table also identifies typical tunneling methods and tunneling depths for each alternative.

The groundwater elevation varies with topography and season in Segment C. A groundwater table is typically encountered at depths between 20 and 100 feet. In some locations of Downtown Bellevue, there is artesian groundwater pressure. These excess pressures would have to be considered when designing and constructing tunnels and elevated structures.

The presence of relatively shallow groundwater in some locations has meant that dewatering wells have been used to lower groundwater during excavation of basements for new highrise buildings in some parts of Downtown Bellevue, such as at the recently constructed Bravern office buildings. Dewatering during construction can increase the potential for settlement where soils are soft or loose and heavily saturated. At these locations the extent of dewatering would need to be monitored closely to avoid damage to buildings, streets, or utilities from settlement induced by dewatering. Previous excavation experience in Downtown Bellevue indicates that loose or soft soils are fairly shallow and localized, thereby limiting this risk relative to other areas.

Segment D

Land within Segment D varies from a relatively level to gently sloping upland area. Several streams travel through the area toward Lake Washington. This area is dominated by light industrial uses and retail businesses. These developments have modified most of the land. Soil conditions consist primarily of layered sand and gravel. In some localized areas, sands and gravels are of loose or medium density, making these soils potentially prone to liquefaction during a large seismic event. Other areas of glacial till are heavily overconsolidated from the weight of past glaciations, resulting in very high bearing strengths and little potential for settlement or liquefaction. There are steep slopes in areas on the south side of SR 520.

The groundwater elevation in the vicinity of NE 12th Street and the former BNSF Railway corridor is located within 10 to 20 feet of the ground surface, as indicated by the water level in Lake Bellevue. In other areas along the alternative, groundwater was typically encountered between the surface and 15 feet deep or at greater depths, between about 45 and 60 feet. In some locations, there are artesian conditions, indicating that water is confined by low-permeability layers.

TABLE 4.11-2
Geological Conditions for Tunnel Alternatives

Alternative	Geotechnical Characteristics	Groundwater Conditions[a]	Types of Tunnels Proposed	Depth of Expected Excavation
Preferred 110th NE Tunnel Alternative (C9T)	Minimal fill except for some localized areas of up to 5 feet of loose fill. Medium dense to very dense glacial till underlain by very dense advance outwash and very stiff to hard clay and silt.	Depth to groundwater is generally between 30 and 50 feet. Near NE 2nd Street, groundwater was encountered in sand lenses between 12 to 28 feet deep.	Cut and cover	Up to 60 feet
Bellevue Way Tunnel Alternative (C1T)	10 to 15 feet of medium dense fill underlain by very dense glacial till and advance outwash.	Depth to groundwater varies between 65 feet and 90 feet.	Cut and cover, SEM under Bellevue Arts Museum	South of NE 6th Street: up to 80 feet East of Bellevue Way: up to 55 feet
106th NE Tunnel Alternative (C2T)	Conditions unknown south of Main Street. North of Main Street there is minimal fill until NE 6th Street, which is up to 17 feet of medium dense advance outwash underlain by very dense advance outwash. Along NE 6th Street, there is up to 15 feet of medium dense fill underlain by very dense glacial till and stiff to hard glacial lake deposits.	Depth to groundwater is approximately 50 feet south of NE 6th Street. At the Bellevue Transit Center Station, no groundwater was encountered in borings up to 90 feet deep. Groundwater depth unknown north of NE 6th Street.	Cut and cover, bored tunnel	Up to 55 feet
108th NE Tunnel Alternative (C3T)	Conditions unknown south of Main Street. North of Main Street is very dense glacial till, advance outwash, and very stiff silt. At the Bellevue Transit Center Station and north to NE 10th Street, there is up to 16 feet of very loose to medium dense fill underlain by dense glacial till and advance outwash and stiff to very stiff glaciolacustrine deposits. North of NE 10th Street, there is up to 15 feet of loose to medium dense fill underlain by very dense glacial till consisting of sand with silt and silty gravel.	Depth to groundwater is approximately 47 feet south of NE 6th Street. At the Bellevue Transit Center Station, no groundwater was encountered in borings up to 90 feet in depth. Groundwater depth unknown north of NE 6th Street.	Bored, except for cut and cover at tunnel portals and stations	Between 80 and 110 feet for bored sections Up to 65 feet for cut and cover tunnels, and 110 feet at cut and cover Bellevue Transit Center Station

[a] Groundwater depths are approximate and can vary by several feet with the season. Development in the area can also change the depth to the groundwater table.

SEM = sequential excavation mining

Segment E

The area within Segment E transitions from a higher ridge to the Sammamish River Valley. Lake Sammamish and the Sammamish River have influenced the geology and soils of this area. Areas to the west of Sammamish River are upland areas dominated by residential and commercial development. Land east of the Sammamish River and south of SR 520 is a low relatively flat valley area containing a large county park. The area east of the Sammamish River and north of SR 520 consists of a relatively flat area developed with residential and commercial structures forming Downtown Redmond. Soil conditions vary between the upland area and the valley area. In the upland area, geological conditions are similar to those in Segment D. In the valley, soils consist of an upper layer of fill, underlain by sand and gravel and layers of soft, compressible peat and clay up to 25 feet deep. These soils are less suitable for construction and some are prone to liquefaction. Dense glacially consolidated soils are located beneath the fill and surface soil deposits. There are steep slopes in areas along the west side of West Lake Sammamish Parkway.

The groundwater elevation varies in Segment E. In the upland area, zones of groundwater are encountered from the surface to 20 feet deep or more. Adjacent to the Sammamish River, groundwater is within 3 feet of the ground surface in undisturbed areas and deeper in areas where fill has been placed. In the valley area, away from the Sammamish River and Bear Creek, groundwater is encountered at about 20 feet deep.

Maintenance Facility Surroundings

Four potential locations have been identified for siting a maintenance facility. Three of these are located in Segment D, and one is located in Segment E. The surface geology and soil conditions at the ground surface in those locations have been modified by human development. Geotechnical characteristics and groundwater conditions are generally as described above for Segments D and E.

4.11.3 Environmental Impacts

This section summarizes the impacts that could result from the East Link Project and the No Build Alternative. The discussion of impacts covers the general impacts that are common to all segments, and then the key impacts for each segment are discussed.

4.11.3.1 No Build Alternative

Under the No Build Alternative, the East Link Project would not be constructed. The existing geology and soils environment would essentially remain unchanged. The existing risk from seismic hazards would still exist. New development would continue to take place, thus resulting in more geologic risk from existing steep slope, erosion, and seismic hazards.

4.11.3.2 Impacts during Operation

Impacts Common to All Build Alternatives

Operational impacts would result from new excavation slopes and new earth fills required for the light rail facilities. Other impacts would be related to geologic hazards that already exist. For example, there would be a risk of seismic events during the period of operation, and this risk could result in other related geologic hazards, such as liquefaction and seismic-induced slope failures. These hazards could represent risks to the public using the light rail facilities if not adequately considered during project design and construction.

Potential long-term operational impacts that are common to each of the segments are discussed in the following subsections.

Insufficient Stability of Earth Slopes and Retaining Structures

Insufficient long-term stability of earth slopes and retaining wall structures could endanger on-site and off-site properties. The earth slopes could include natural slopes, slopes that have been steepened to meet alignment requirements, or slopes for embankment fills. This risk would be greater if a large seismic event were to occur.

The overall risk of impacts from slope and retaining wall failures would be low for all alternatives. Slope and retaining wall stability would be considered during the design phases of the project, and various mitigation measures could be implemented to stabilize areas of potential risk.

Seismic Ground-Shaking

The project study area is within a seismically active area. Consequences of a seismic event occurring during operations would be strong ground-shaking, which would cause increased inertial loading and movement within structures supporting the light rail system. The ground-shaking could also lead to liquefaction of loose, saturated, cohesionless soils; settlement from densification of loose soils; instability of steep slopes; or increased earth pressures on retaining walls. These impacts could damage the constructed light rail facilities and endanger people using the facility.

The elevated light rail support systems and earth-retaining structures, including retained fills or cuts, would be designed for both the seismic ground-shaking level and the consequences from ground-shaking. The East Link Project would meet current seismic design standards required to minimize the long-term risks to the system and the public. These standards are based on the occurrence of a very rare seismic event.

The tunnel alternative should perform well during strong ground-shaking based on the performance of tunnels around the world during past earthquakes when appropriate designs were applied. The latest seismic design methods would be used to ensure good performance.

Long-Term Settlement from New Earth Fills

New earth fills would be used in some areas to meet track-grade requirements. Walls would typically be used to retain the fill, thereby minimizing the area covered by fill. The fill would cause new earth loads on the existing soil, which could lead to settlement of soft soil.

Settlements from new earth loads could occur in areas that have soft surface soils. Although settlement-prone soils could occur anywhere along the alternatives, the areas of primary concern are near Mercer Slough, near Lake Bellevue, and in the Sammamish River valley where soft, compressible soils have been identified. Where glacially consolidated soils occur at the ground surface, the potential for settlements from new earth loads would be minimal because these soils have already been compressed by the weight of ancient glaciers.

The new earth loads would cause compression of soft soils below and adjacent to the new construction. The extent of compression beyond the footprint of the new earth load can extend 20 feet or more from the load. The impacts on adjacent areas could include the following:

- Settlement of buildings or residential structures
- Damage to roadways and sidewalks, resulting in additional maintenance work
- Damage to buried utilities located next to new fill

Additional geotechnical assessment during final design would be focused on identifying the location of these soft soils. Where found, they could either be replaced, or ground improvement techniques would be used to prevent long-term settlement. Another option in some locations would be to use lightweight fill rather than normal earth fill. These lightweight materials include extruded polystyrene (geofoam) or cellular concrete.

Settlement of compressible soils beneath proposed retaining structures and fill areas could require periodic maintenance of the new infrastructure, which could minimize potentially poor ride quality when maintenance is not performed. Utilities or other structures located adjacent to the new facilities could also settle as a result of increased loads. Over much of the project corridor, the existing soils would provide excellent bearing support, and the potential for long-term settlement would be negligible. In areas where settlement-prone soils exist, mitigation measures would be used to avoid the detrimental impacts of settlements.

Summary

The degree of the impacts described above in each segment would depend on the specific site conditions, development plans, and final design. In all cases, the severity or frequency of the hazard or impact could be avoided or minimized using conventional design and construction methods. Where impacts are found to be moderate to high, more effort would be required during design to evaluate the severity of the impact and identify an adequate avoidance or minimization method. The most important geologic hazard for operations would result from seismic ground-shaking, which would affect all segments, although the hazard would be slightly higher in Segments A and B because of their proximity to the Seattle Fault Zone where the risks from fault movement and ground-shaking are higher. In other segments, the primary seismic hazard would be associated with ground-shaking and secondary impacts of ground-shaking, such as liquefaction, slope failures, and ground settlement.

Segment A

Preferred Interstate 90 Alternative (A1) travels along the existing I-90 roadway in the current HOV lanes. The route would offer overall stable geology and soil conditions during operation except in a limited number of areas. The primary geologic hazards would be strong ground-shaking from a large seismic event in the region or rupture of the Seattle Fault. Portions of the Rainier Valley and the east approach of the I-90 floating bridge are the most vulnerable areas for these hazards. The potential for fault movement along the Segment A route is believed to be very low because of the unlikely occurrence of a rupture and the low likelihood that any fault displacement would occur along the track alignment.

Segment A includes the use of the I-90 existing structures, which were designed during the 1970s and mid 1980s. These structures were designed to meet seismic requirements at the time of construction in the early 1980s. The light-rail system design would be such that placing the light rail on the I-90 structures would not increase their seismic vulnerability.

Sound Transit also commits to funding retrofits necessary to meet current earthquake-resistant structural design requirements. Structures assumed to be retrofitted include the columns, bridge seats, and restrainers for the light rail portions of the D2 Roadway, Rainier Avenue overcrossing, approach spans to the floating bridge, and the East Channel Bridge. These retrofits would be accomplished using current Federal Highway Administration (FHWA)/ American Association of State Highway and Transportation Officials (AASHTO) policies, consistent with WSDOT's own practices for retrofitting existing structures. The floating bridge is generally not vulnerable to seismic events due to the dampening effect of the lake water.

Segment B

Along Bellevue Way SE, *Preferred 112th SE Modified Alternative (B2M)* includes elevated, at-grade, and retained cut portions. This alternative would not affect the slopes on the west side of Bellevue Way SE. However, retaining walls would be required to support the cuts along much of the length on the east side; heights of these retaining walls could be greater than 20 feet. Deposits of liquefiable soils occur in some locations along the Bellevue Way SE portion of the *Preferred Alternative B2M* route. These soils would be replaced or improved. Ground improvement measures could include the use of vibrodensification

Vibrodensification is a ground improvement process used in cohesionless soils to make the soil denser. The vibrator action, usually accompanied by water jetting, reduces the intergranular forces between the soil particles, thereby allowing the soil particles to move into a denser configuration. Compaction can be achieved above and below the water table.

methods, the installation of stone columns, or cement deep soil mixing.

The South Bellevue Park-and-Ride Lot would likely be supported on drilled shaft foundations. This type of foundation is routinely used in the Puget Sound area. The depth of the drilled shaft would extend to glacial tills located within 50 feet of the ground surface.

Preferred Alternative B2M would be located within a lidded, below-grade, retained cut next to the Winters House. The retained cut would consist of retaining walls to support soil on either side of the track. Soils along the retained cut and supporting the Winters House are competent silts, sands, and gravels. Construction methods would be selected to prevent vertical or lateral movement of the soil, thereby minimizing potential for settlement of Bellevue Way SE and of the Winters House.

The retaining walls used to construct the retained cut would potentially create a barrier to groundwater flow originating from west of Bellevue Way SE. However, the sealed, concrete-lined retained cut would prevent groundwater from entering the retained cut but would allow groundwater to flow down-gradient beneath the cut. Additional potential mitigation measures are discussed in Section 4.9, Water Resources.

The *Preferred Alternative B2M* route along 112th Avenue SE runs along one of the Mercer Slough channels (Mercer Slough West) located just to the east of the planned route. Soils generally comprise a limited depth of fill over glacial till except in the vicinity of SE 15th Street, where a deeper thickness of soft material was encountered.

This section of the route would have retaining walls and embankment fills to meet track-grade requirements. Additional slope stability, settlement, and localized liquefaction issues would be implemented with this alternative compared with the alternatives within the median of 112th Avenue SE.

Preferred Alternative B2M would potentially involve maintenance issues adjacent to the north end of the Mercer Slough from long-term settlement of soft clays and peats and would be at a higher risk from liquefaction of saturated sands in Mercer Slough than other Segment B alternatives.

The other Segment B alternatives include at-grade and elevated alternatives located in south Bellevue. These alternatives also would potentially be impacted by ground conditions, as discussed below.

Within Segment B, at-grade alternatives adjacent to the north end of Mercer Slough (112th SE At-Grade Alternative [B2A], 112th SE Bypass Alternative [B3], and Alternative B3 - 114th Extension Design Option [B3 - 114th Design Option]) would potentially involve more maintenance issues because of long-term settlement of soft clays and peats. These alternatives would be at a higher risk for liquefaction in saturated sands than the Bellevue Way Alternative (B1) that runs along Bellevue Way SE and the 112th SE Elevated Alternative (B2E) that is elevated with foundations in competent load-bearing soils.

The slopes along Bellevue Way SE and 112th Avenue SE would require the use of retaining walls to accommodate the roadway widening for the rail system for Alternatives B1, B2A, B3, and B3 - 114th Design Option and *Preferred Alternative B2M*. Heights of the walls are generally limited to 20 feet or less and can be designed to provide long-term stability, even where slopes are located above the walls. Alternative B2E would generally involve fewer cuts into existing slopes than alternatives that have at-grade sections (Alternatives B1, B2A, B3, and B3 - 114th Design Option and *Preferred Alternative B2M*) and, therefore, would involve less risk for long-term slope failures. The grade changes along 112th Avenue SE (with Alternatives B2A, B3, and B3 - 114th Design Option and *Preferred Alternative B2M*) are lower than along Bellevue Way SE (with Alternative B1), suggesting that the 112th Avenue SE alternatives would involve less risk from a sloping ground standpoint.

The BNSF Alternative (B7) includes an elevated structure across Mercer Slough. Soils along the slough consist of very soft peats and clays to a depth of 60 to 100 feet. Support for an elevated structure at the center of the slough crossing would have to be developed at depths of greater than 120 feet because of the thickness of soft soils.

Results of a geotechnical WSDOT monitoring program also show that soils move towards the center of the slough during annual changes in water levels within Lake Washington. The extent of movement has resulted in large soil loading to existing WSDOT bridges, forcing WSDOT to implement special bridge repairs to maintain operation and safety of their bridges.

The slough crossing for Alternative B7 would have to be designed to accommodate these soils loadings. Furthermore, Sound Transit would have to consult closely with WSDOT to ensure that the locations of the Sound Transit structures do not increase loads on existing WSDOT I-90 structures. Elevated structures would also be required for Alternative B7, beginning about one-half mile south of SE 8th Street, to meet grade requirements and because of the likelihood of encountering soft, compressible soils in the upper 10 to 30 feet near SE 8th Street. The potential for failure of steep slopes along Alternative B7 between Mercer Slough and I-405 from seismic loading or from natural processes (e.g., periods of heavy rainfall) would be a higher risk to the light rail system during operations than they would be for other Segment B alternatives because of the greater steepness, height, and length of these slopes.

Segment C

The geology and soils conditions along the *Preferred 108th NE At-Grade Alternative (C11A)* route are generally stable. Soils consist of fill, underlain by deposits of glacial till consisting of silt, sand, and gravel.

Retained fill profiles, which are required for elevated structures along the *Preferred Alternative C11A* route, would result in new earth loads. However, soils underlying the *Preferred Alternative C11A* route are glacial till soils that are compact and pose little risk of settlement. These good conditions extend across I-405 and along the former BNSF Railway corridor south of Lake Bellevue.

For *Preferred 110th NE Tunnel Alternative (C9T)*, a shallow cut-and-cover tunnel would be constructed along 110th Avenue NE. The tunnel depth would range from 40 to 60 feet below the ground surface, depending on location. Soils along the tunnel route generally consist of a layer of fill material over glacial till. The glacial till consists of very dense silts, sands, and gravels. Occasional boulders could occur in this material. These soils are generally compact and pose little risk of settlement.

Obstructions from existing soil nails and tieback anchors used in the construction of the below-grade structures would need to be considered with *Preferred Alternative C9T*, but this alternative would avoid some of the risk of nearby building settlement by having the base of the tunnel at or just slightly below the foundations for the nearby buildings.

The other Segment C alternatives include at-grade, elevated, and tunnel profiles. The geology and soil conditions within Segment C would be generally stable for all alternatives and would not differ substantially for at-grade, elevated, and tunnel profiles. Although ground conditions are generally good and similar for these other alternatives, some difference in the potential for impacts would occur, as discussed below.

The at-grade alternatives (Couplet Alternative [C4A] and 110th NE At-Grade Alternative [C9]) routes are similar to *Preferred Alternative C11A* and generally would have a low risk for long-term settlement during operations because the at-grade track would cause very little change in load to the soils and the soils are relatively strong, with good load-bearing characteristics.

Retained fill profiles, which are required for transition to elevated structures (112th NE Elevated [C7E], 110th NE Elevated [C8E], and 114th NE Elevated [C14E)] Alternatives and *Preferred Alternative C11A*), would result in new earth loads, which could lead to minor long-term settlement and increased maintenance requirements. However, in most locations, the existing soils are relatively incompressible because they are composed of glacial till and can support the loads without detrimental settlement. Alternatives C7E and C8E would have the lowest risk for long-term settlement during operations because of the foundation types used for elevated structures, in combination with good bearing characteristics of the soil along these alternatives.

The other tunnel alternatives (Bellevue Way Tunnel [C1T], 106th NE Tunnel [C2T], and 108th NE Tunnel [C3T] Alternatives) are designed to avoid other underground obstructions from building developments and take advantage of the stable glacial till geologic layers. Long-term settlement of nearby structures would be an important design consideration for these alternatives.

Segment D

Soils along the *Preferred NE 16th At-Grade Alternative (D2A)* route consist primarily of a thin layer of fill over very competent glacial till.

Sections of *Preferred Alternative D2A* that require additional fill to meet grade would have more risk for long-term settlements than sections of the alternatives already at-grade and the NE 16th Elevated (D2E) and the SR 520 (D5) Alternatives because these alternatives are mostly elevated, resulting in fewer areas that would require fill and, therefore, fewer areas of additional load and potential long-term settlement.

Preferred Alternative D2A also has retained cuts under 120th and 124th Avenues NE and retained cuts at the 120th Station. There is a risk for potential settlement behind the walls if the retained cuts move; however, the glacial till in the area is very competent, so the likelihood for movement in the retained cuts is believed to be small.

Preferred Alternative D2A would be located on slopes adjacent to SR 520; therefore, designs would include precautions to address slope stability during a seismic event, and soil movement at column locations.

Preferred Alternative D2A includes a storage track north of the NE 12 Street undercrossing and where the track alignment turns from north-south to east-west. Soils along the tail-track section generally consist of a thin layer of fill over very competent sands and gravels. This section of the track was used for many years by BNSF Railway without impacts from local soils and geology; therefore, the tail track would have few impacts to or from soils and geology. Planned development associated with the tail track (i.e., parking area and a small building) also appear to be suitable for the soils and geology in this area.

The other Segment D design options include at-grade, retained cut, and elevated alternatives located in east Bellevue and west Redmond. Soils along the Alternative D2A - 120th Station Design Option and the Alternative D2A - NE 24th Design Option are similar to *Preferred Alternative D2A*. These soils consist of a thin layer of fill over very competent glacial till. Potential impacts associated with these design options are as summarized below.

The D2A - 120th Design Option has the same footprint location but has at-grade crossings and an at-grade station, which would overall be lower risk than retained-cut crossings and a station constructed using retained cuts because there is not the potential for cut-slope movement and potential settlement behind retaining walls.

The D2A - NE 24th Design Option has at-grade and elevated components. The fills for this design option would overall be minor, but there would be an approach fill supported by a mechanically stabilized-earth (MSE) wall from the elevated structure to at-grade. New earth loads from the fill could result in settlement of the approach fill, the adjacent roadway, and utilities located near the new fill. Soils in this have very good load bearing characteristics; therefore, the potential for settlement would be low. The D2A - NE 24th Design Option also runs along NE 24th Street rather than along SR 520, thus avoiding some of the slopes along SR 520 and having a lower risk for slope movement during a seismic event than *Preferred Alternative D2A*.

Like the other segments, the geology and soil conditions for other alternatives within Segment D would be generally stable for all alternatives and would not differ substantially for at-grade and elevated profiles. Potential impacts associated with these alternatives are summarized discussed below.

The NE 16th Elevated (D2E), NE 20th (D3), and SR 520 (D5) Alternatives are at-grade, within retained cuts, on retained fills, or elevated. Sections of the alternatives could also involve localized areas with steep slopes. The good bearing characteristics of the soil along Segment D would limit the long-term impacts from any of these types of construction.

Sections of Alternative D3 that require additional fill to meet grade would have more risk for long-term settlements than *Preferred Alternative D2A,* Alternative D2E, and sections of all alternatives already at-grade. Retained cuts would also be required in some areas and for substantial portions of Alternatives D3 and D5, and there would be some chance of settlement behind these cuts.

Alternative D5 has the most area of steep slopes compared to the other Segment D alternatives. Areas with steep slopes would need to be evaluated for long-term stability, and the potential impacts of seismic events would have to be established. The seismic loading impacts could include areas of localized liquefaction, seismic-induced settlement, or slope failures.

Segment E

Along the *Preferred Marymoor Alternative (E2)* route, soil conditions to the west of the Sammamish River are competent, which are similar to those along the Segment D routes. However, from just west of the Sammamish River to the east, the *Preferred Alternative E2* route is located in an area that has a low to moderate potential for seismic hazards due to sand and silt layers in the Sammamish Valley and a moderate potential for erosion and slope failures from steep slopes heading into the valley. Areas within the valley could also be prone to settlement of peat deposits.

The Alternative E2 - Redmond Transit Center Station Design Option is located in the Sammamish Valley and includes an additional station. Subsurface soils are similar to *Preferred Alternative E2*, and these soils have a low to moderate potential for seismic hazards, such as liquefaction and liquefaction-related settlement, and could also be prone to settlement of peat deposits. There would be a slightly higher risk of long-term settlement for the E2 - Redmond Transit Center Design Option because this design option has an additional station and a longer route, which increases the areas that could settle compared to *Preferred Alternative E2*.

The geology and soil conditions for other Segment E alternatives would be generally stable and not differ substantially for at-grade and elevated profiles. Although ground conditions are generally good and similar with these other alternatives, some differences in the potential for impacts would occur, as discussed below.

The Redmond Way (E1) and Leary Way (E4) Alternatives routes are in areas of geologic and soil conditions similar to the eastern portion of *Preferred Alternative E2*.

All of the Segment E alternatives generally have similar segment components: at-grade, retained cut, and elevated. Alternative E1 is located within more areas of steep slopes than *Preferred Alternative E2*, E2 - Redmond Transit Center Design Option, or Alternative E4, and would be at a higher risk for long-term erosion and slope instability compared to these alternatives and design option.

Maintenance Facilities

The 116th (MF1), BNSF (MF2), and SR 520 (MF3) maintenance facility locations in Segment D could have lower impacts (fewer settlement and seismic issues) than the SE Redmond Maintenance Facility (MF5), which would be located in Segment E where soils are more compressible and prone to liquefaction.

4.11.3.3 Impacts during Construction

Impacts Common to All Build Alternatives

Impacts during construction are associated with the equipment used to perform the construction, as well as the direct and indirect impacts of the construction activities. Construction activities have the potential to cause a number of geology- and soils-related short-term impacts on the environment. These construction impacts are often quite similar to the operation impacts discussed previously in Section 4.11.3.2, and therefore are only briefly described below.

Erosion Hazards

Clearing vegetation; placing fill; and removing, grading, or stockpiling spoils during construction allows rainfall and runoff to erode soil particles. The severity for erosion to occur is a function of the area of exposed soil, rainfall intensity and duration, soil characteristics, and the volume and configuration of soils stockpiled. BMPs that could help minimize erosion hazards include, but are not limited to, the following:

- Maintaining as much vegetation as possible and designing surface water runoff systems
- Constructing silt fences downslope of all exposed soil and using straw, mulch, or plastic covering over exposed earth
- Using temporary erosion control blankets and mulching to minimize erosion prior to vegetation establishment

Slope Instability Hazard

Construction of the proposed infrastructure would involve grade changes, cuts and fills, or installation of bridge and retaining wall structures that have the potential to cause hillside slumping. Overall risk of impacts due to constructing in steep-slope or landslide hazard areas would be limited for all alternatives due to the limited number of existing steep slopes along the proposed alternatives.

Detailed slope stability evaluations would be conducted during design, and where appropriate, methods of stabilization developed. Methods that could help minimize slope stability hazards include, but are not limited to, the following:

- Use of retaining structures that are designed for the loads from moving soils
- Use of mechanical slope reinforcement such as soil nailing
- Construction specifications and quality assurance programs that prohibit oversteepened slopes

Seismic Ground-Shaking

An earthquake could occur during construction, resulting in strong ground-shaking throughout the region. This shaking could lead to embankment slope failures, liquefaction, or ground settlement. The risk of seismic hazards to construction is considered low because there is a low probability that an earthquake would occur during the actual construction period.

If a large earthquake were to occur, the major risk would be to the ongoing construction activities. Work schedules would likely be delayed as efforts are made to repair damaged components of the work. Some disruption could also occur to utilities or nearby structures from the damage to exposed cuts or fills.

Construction-Induced Vibrations

The use of heavy equipment during construction causes ground vibrations. The level of vibrations depends on the type of heavy equipment, distance from the source, and ability of the soil to transmit vibrations. The main concerns for construction vibration are the annoyance to people working and living in the area when vibrations can be felt and the potential damage to structures if vibration levels are excessive.

Although most construction processes do not generate high enough vibration levels to approach damage criteria, damage could occur with certain procedures, and there could be a perception that vibrations are causing damage. The major sources of construction vibration might include vibratory ground improvement, stone column construction, impact pile-driving, earth excavation in hard ground, and vibratory rollers for subgrade compaction.

Drilled shafts would generally be used for deep foundations, and minor levels of vibration are normally associated with this foundation construction method. The only activity with the potential to cause building damage is ground improvement (e.g., vibrodensification or stone columns) if carried out near structures. Alternate ground improvement methods or structural foundations would be used where there would be risk of structural damage from ground improvement. Contract documents would also require the contractor to monitor vibration levels during construction near sensitive buildings and, if levels exceed allowable limits, alternate construction methods would be required. Section 4.7, Noise and Vibration, provides a detailed review of these potential impacts.

Settlements from New Earth Loads
New earth loads would occur during construction from the temporary stockpiling of earth materials and from placement of permanent fills to meet track grade requirements or as approach fills for elevated structures. These new loads would cause immediate soil settlement. The amount of this settlement would depend on the amount of earth load and the compressibility of the soil. In areas where soft, cohesive soils exist, the settlement could continue after the end of construction, as discussed previously in Section 4.11.3.2, Impacts during Operations.

The impact during construction from the new earth loads would potentially include settlement of nearby buildings and residential structures, roadways and sidewalks, and utilities. Design studies would be conducted to quantify the relative amounts of settlement occurring during construction versus operations, and contract documents would describe what the contractor must do to anticipate construction settlements and repair of damage caused by these settlements. Methods for mitigating these impacts are the same as those described previously in Section 4.11.3.2.

Excavations for Foundations and Removal of Unsuitable Material
Excavations for structure foundations and relocation of utilities, if not supported correctly, could result in failure and collapse of the ground next to the excavations, causing damage to buried utilities and to structures or roadways adjacent to the excavations. The potential for adverse impacts on utilities and buried structures is considered low during construction.

Methods that could help minimize utility and buried structure impacts include, but are not limited to, the following:

- Relocating or supporting utilities where utilities are located in the area of excavation
- Using appropriate excavation-support systems, such as temporary retaining walls or trench boxes, which prevent soil movement for locations with utilities outside the zone of excavation
- Preventing the use of certain equipment by the contractor, if the equipment could lead to soil densification

Existing soils excavated during construction that cannot be used as structural fill or for landscape material would require removal from the project footprint and disposal elsewhere. Disposal of the material at off-site locations would result in additional truck traffic, dust, and other construction-related impacts.

Table 4.11-3 shows waste volumes, which include potential soil excavation volumes. These estimates include all excavation, not just unsuitable soils. The estimated total number of truck trips associated with construction of the alternative is also provided. This estimate includes truck trips for bringing in construction materials, including concrete, as well as trips to haul waste volumes.

Dewatering
Dewatering of excavations located below the groundwater table during construction could result in settlement of nearby structures, if proper consideration is not given to the impacts of water level changes. This impact would most likely be associated with Segment C for the cut-and-cover tunnel alternatives but could also include the retained cut at the Winters House and along Bellevue Way SE. Underground construction for the tunnel and stations could also require dewatering if the combination of permeable soils and high groundwater elevation occurs at, for example, a station location.

The primary dewatering impact could be settlement of nearby buildings, roadways, and utilities. The dewatering impact is considered low if proper avoidance and minimization measures are used. Methods that could help minimize soil settlement during dewatering include, but are not limited to, the following:

- Controlling the changes in groundwater elevation near critical structures by using localized dewatering and groundwater injection methods
- Using sheetpile barrier systems to control the horizontal extent of groundwater withdrawal
- Installing deep foundations systems to support the structure during settlement

TABLE 4.11-3
Estimated Waste Volumes and Truck Trips

Alternative	Estimated Soil Waste (cubic yards)	Estimated Total Truck Trips [a]
Segment A		
Preferred Interstate 90 Alternative (A1)	32,500	11,040
Segment B		
Preferred 112th SE Modified Alternative (B2M) to *C11A*	396,900	67,060
Preferred 112th SE Modified Alternative (B2M) to *C9T*[b]	385,200	68,990
Bellevue Way Alternative (B1)	248,300	34,010
112th SE At-Grade Alternative (B2A)	206,300	32,480

Preferred Marymoor Alternative (E2)	521,300	79,020
Alternative E2 - Redmond Transit Center Station Design Option	647,900	89,390

TABLE 4.11-3 CONTINUED
Estimated Waste Volumes and Truck Trips

Alternative	Estimated Soil Waste (cubic yards)	Estimated Total Truck Trips [a]
Redmond Way Alternative (E1)	591,100	82,950
Leary Way Alternative (E4)	560,800	77,930
Maintenance Facilities		
116th Maintenance Facility (MF1)	1,365,400	108,000
BNSF Maintenance Facility (MF2)	406,800	32,040
SR 520 Maintenance Facility (MF3)	599,800	47,350
SE Redmond Maintenance Facility (MF5)	193,600	18,430

Note: Quantities assume all excavation would be wasted. Amount that could be used on site would be defined as design proceeds. The volume of waste is only for the currently known quantities. There is a significant amount of material of which the quantity is unknown that is not contained in this calculation. The quantities only include amounts that can reasonably be estimated at this time.

The number of truck trips is based on trips to remove waste soil, trips to import concrete and other construction materials, and miscellaneous construction travel. Actual numbers would vary depending on the types of equipment used by contractor and the amount of material that would be reused on site.

[a] Includes trips for excavated soil, concrete supply, and other construction materials**.**

[b] Under the C9T - East Main Station Design Option connecting from *Preferred Alternative B2M*, waste volumes and truck trips associated with the SE 8th Station in Segment B would not occur; instead, a similar waste volume and number of truck trips would be expected for the East Main Station in Segment C. The total waste volume and number of truck trips for these two segments combined would, therefore, be approximately the same as with *Preferred Alternatives C9T* and *B2M*.

Summary
The severity or frequency of the construction hazard or impact could be avoided or minimized using conventional design and construction methods. Where impacts are identified as being moderate to high, more effort would be required during design to evaluate the severity of the impact and identify an adequate avoidance and minimization method.

The most important geologic hazard during construction would be erosion control, which would need to be appropriately addressed in all segments. Alternatives with steep slopes would require more consideration than relatively flat areas. Some common methods of erosion control include installing silt fences, providing sedimentation ponds, covering soil, and limiting amounts of exposed earth during wet winter months.

Segment A
As stated previously in Section 4.11.3.2, Sound Transit anticipates seismic retrofits for some I-90 structures that would be used by East Link. This may include in-water work in Lake Washington to reinforce the existing structures. New construction on I-90 would involve impacts that are common to all build alternatives, such as erosion, slope instability, construction vibrations, settlement from new earth loads, and excavation for foundations.

Segment B
Preferred Alternative B2M would have more erosion hazards, slope stability, settlement, and localized liquefaction issues compared with the alternatives within the median of Bellevue Way SE (Alternatives B1, B2A, and B2E) or Alternative B7.

Soil improvements would have to be conducted at the edge of Mercer Slough; therefore, special construction methods would be required to protect the slough from construction impacts, such as erosion of exposed soil and slope instabilities.

Special consideration will be required for construction impacts near the Winters House. The proximity of the excavation to the Winters House would require vibrations associated with construction to be very low and for rigid lateral support systems to be used to prevent settlement of the Winters House when excavating to the track grade.

The alternatives associated with 112th Avenue SE in Segment B, including Alternatives B2A, B2E, and B3 and the B3 – 114th Design Option, have flatter slopes and would be expected to have fewer erosion and landslide issues during construction than with

Alternative B1, where some steep slopes exist. However, there are more locations along 112th Avenue SE (along the *Preferred Alternative B2M* route) where soils are believed to be generally softer at the ground surface than soils within the median of Bellevue Way SE (along the Alternative B1 route), and these softer soils are more susceptible to construction-related issues in areas where fills are placed or where foundations for elevated structures must be constructed. The potential slope and erosion issues along Bellevue Way SE (along B1 route) would likely be easier to address than soft soil conditions along 112th Avenue SE.

Alternative B3 and the B3 - 114th Design Option cross Sturtevant Creek and would, therefore, traverse additional areas of soft soils and shallow groundwater conditions compared to the other alternatives. Soft soils and shallow groundwater are more susceptible to construction-related issues such as dewatering and settlement.

With Alternative B7, special methods would be required for protecting wetlands during construction. Existing WSDOT I-90 structures would also need to be protected from soil loads caused by construction of work trestles, foundations for elevated structures, and other construction requirements within the slough, including potential loads from altering the flow of peat during annual changes in water level within Lake Washington. Finally, design precautions would be taken to address the steep slopes along the west side of the former BNSF Railway corridor, which could pose a risk to construction and to the public using 118th Avenue SE.

Segment C

Tunnel Options

Preferred Alternative C9T is a shallow cut-and-cover tunnel. (Tunnel construction methodology is described in Section 2.4.5 of Chapter 2.) This alternative would be shorter than the other tunnel alternatives, thus producing less soil waste and fewer truck trips; however, there could be more construction issues related to excavation support of buildings, potential need for temporary excavation dewatering, construction vibrations, and potential for roadway damage from ground settlement compared to the deep bore tunnels. The three other alternatives that would involve tunneling (Alternatives C1T, C2T, and C3T) would be constructed by various methods, including using a tunnel-boring machine, sequential excavation mining (SEM), and cut-and-cover methods; Tunneling alternatives within Segment C could result in settlement of the ground above or adjacent to the tunneling work from loss of ground volume. The risk of tunnel-related settlements could include damage to roadways and utilities, residential structures, and buildings.

Loss of Ground Volume

Loss of ground volume refers to the amount of excavated soil in excess of the calculated geometry of the tunnel. If a greater volume of material is excavated than is displaced by the tunnel, then this material was lost from around the tunnel, which could create adverse impacts.

Loss of ground volume could occur with tunnel boring machines (with Alternative C3T) and SEM (with Alternative C1T under the Bellevue Arts Museum) when the amount of soil removed along the path of the tunnel excavation exceeds the planned diameter of the tunnel, resulting in loose zones or voids in the soil behind the tunnel liner. These voids or loose zones in the soil could progressively migrate upward and eventually result in loss of foundation bearing support for any building, utility, or roadway located above the void or loosened soil. The reduced bearing support could result in settlement of any structure supported on the zone of loosened soil or void. Loss of ground is most often encountered in poorly graded sands and gravels located below groundwater, where flowing or raveling ground conditions can develop. Settlement of ground can also occur with the cut-and-cover method of tunnel construction if tunnel side walls cannot support the earth and nearby building loads during ground excavation, leading to settlement of the ground behind the tunnel walls as the wall deflects into the excavation. Alternative C2T would have the least potential for settlement because of the denser substrate underlying its route.

The magnitude of acceptable settlement would depend on the type and dimension of the structure but is generally on the order of 1 inch or less. The settlement is greatest above the centerline of a bored tunnel and decreases outward. Typically, the settlement extends horizontally from the tunnel centerline no more than three times the tunnel diameter, which would be approximately 75 to 85 feet. For a cut-and-cover tunnel, the potential for settlement above the centerline is reduced because of the construction method; however, a potential for settlement would exist behind the tunnel walls. This distance could extend a distance equivalent to the height of the cut-and-cover tunnel, which could be as much as 45 feet. In areas where retained cuts would be used for access to tunnel sections of the alternative, the potential for settlement behind the retaining walls also would exist. Although Alternative C3T would be primarily a bored tunnel, cut-and-cover construction would still be necessary for construction of the Bellevue Transit Center station with this alternative. These potential risks can be minimized by implementing standard design methods and industry best practices, including detailed geotechnical explorations and groundwater evaluations.

Additional geotechnical engineering explorations during final design would be used to select specific tunnel construction methods that control the potential for ground settlement. Because of the nature of the glacial soils along the tunnel alternatives, limited settlement is expected during and after construction. However, localized zone of running sands and raveling gravels could be identified during explorations or encountered during tunneling, which could require special tunnel construction methods. These methods would include treating areas of loose soils by permeation or jet grouting, carefully controlling the steering of tunnel machines to avoid overexcavation of the tunnel diameter, monitoring of the volume of excavated material, using ground conditioning systems to prevent ground loss, controlling conveyor discharge of sands and gravels under groundwater pressure, and compaction or consolidation grouting to compensate for lost ground.

Design and construction would also consider the potential impacts of groundwater elevation changes—either temporary or permanent during and after tunnel construction. Groundwater occurs at or above the tunnel horizon for most of the tunnel alternatives; in parts of Downtown Bellevue, artesian groundwater conditions exist, meaning that the groundwater pressure head is above the ground surface. In many areas groundwater is “perched” on fine-grained material, isolating it from recharge sources. These conditions would potentially affect the selection of tunneling methods and could require localized dewatering, which has the potential to cause subsidence or settlement in soft or loose soils. The potential for settlement from dewatering is higher when soils are loose, tunnels are shallower, excavations for stations are deeper, and adjacent building foundations are shallow. Where soil is settlement-prone, measures could be implemented to limit the settlement from groundwater changes to tolerable levels. These measures could include reinjecting water or using impervious cutoff walls to limit the zone of groundwater elevation change.

During construction, adjacent structures and surface areas would be monitored where there is a potential for settlement. Where critical conditions are identified, it may be necessary to underpin buildings to prevent building settlement or to use active wall bracing systems in the case of cut-and-cover tunnels. These active bracing systems would apply bracing forces to the side walls of the cut-and-cover tunnel to adjust for any tendency to deflect into the excavation as earth is removed in front of the tunnel walls. Prior to and following construction, Sound Transit would conduct detailed inspections of nearby buildings, residences, and utilities to establish conditions before and after construction. Although no damage to structures is anticipated from the tunneling work, any damage that occurs would be repaired.

Raveling Gravels

Raveling gravels are gravels that have very little fines (clay or silt particles). When excavated, they tend to roll downward to the angle of repose of the material. This is a common problem on exposed slopes, where coarse material progressively moves down the slope.

At-Grade and Elevated Options
Preferred Alternative C11A has at-grade, elevated, and retained cut components. Generally good geologic conditions occur along this alternative. Standard construction methods would be used because of the good soils, minimal loading, there would be no deep excavations, and no geologic concerns exist.

For Alternative C4A, relatively standard construction methods would be used because it would be mostly at-grade, and no geologic concerns exist.

Alternatives C7E and C8E both would be elevated systems with at-grade and retained-fill components. Standard construction techniques of retaining walls and compaction methods would be used to address settlement impacts from new earth loads.

The Alternative C9A route, which is similar to the *Preferred Alternative C11A* route except that it follows 110th Avenue NE instead of 108th Avenue NE, also has geologic conditions similar to *C11A*.

Alternative C14E would be an entirely elevated system. Standard retaining wall construction techniques and compaction methods would be used to address settlement impacts from new earth loads from retained fil**ls**.

Segment D

Soils are typically good along the *Preferred Alternative D2A* route; however, there are some soft soils adjacent to Kelsey Creek and the Kelsey Creek tributaries. *Preferred Alternative D2A* is elevated across the tributaries to Kelsey Creek, thereby reducing the potential for settlement compared to an at-grade alternative in this area. Retaining walls would be used to retain fills to meet track grade requirements. If the retaining walls are not designed correctly, settlement could occur behind the wall.

The station at 120th would be in a retained cut 20 feet below grade, but subsurface soil conditions are good for this type of construction. Retained cuts under the 120th and 124th Avenues NE crossings would also be in subsurface conditions that are suitable for this construction type. Retained cut walls for the 120th Station and for the bridges can be constructed with limited construction vibrations and noise, but the cuts would produce excavated materials that would require removal from the area. *Preferred Alternative D2A* would be constructed along slopes adjacent to SR 520, which makes construction activities more difficult than constructing on a flat-grade.

There are some locations with artesian conditions along the alternative that would have to be considered during design and construction of the elevated structures foundations; however, methods for accomplishing such construction are available and have been used in the Puget Sound area.

Impacts during construction of the tail track would be limited because the track system is in place and has been used in the past by heavy rail. Soils at the planned location of parking area and the building should have limited impacts, as long as normal BMPs for erosion control are implemented.

The at-grade Alternative D2A – 120th Station Design Option would be less of a risk to construct than *Preferred Alternative D2A* at the same location because it would not require retaining walls to meet the track grade requirements. The at-grade option also would not produce nearly as much excavated soil that would require removal from the area.

Alternative D2A - NE 24th Design Option would run east down NE 24th Street and then north on 152nd Avenue NE, avoiding some of the slopes adjacent to SR 520.

Alternative D5 appears to have the least amount of risk of the Segment D alternatives for all impact categories, except for the soils along its route, which would have a higher erosion potential along the south side of SR 520 compared to the other Segment D alternatives.

Segment E

Preferred Alternative E2 would cross a hillside that has a moderate potential for erosion and slope instability from steep slopes heading into the valley and a low to moderate potential for liquefaction and settlement in the valley. Available information suggests that the Downtown Redmond Station site is underlain by soft soils that would potentially require ground improvement or deep foundations.

Alternative E2 - Redmond Transit Center Design Option would present a slightly higher risk than *Preferred Alternative E2* during construction because of the additional station at Redmond Town Center. However, both the Redmond Town Center Station and the Downtown Redmond Station would be able to use similar, commonly used construction methods.

Alternatives E1 and E4 are in areas of similar geologic and soils conditions to that of *Preferred Alternative E2* and the E2 - Redmond Transit Center Design Option, and no distinct differences were identified.

Maintenance Facilities

The primary construction impact for the maintenance facilities would be soil erosion, except at the SE Redmond Maintenance Facility.

- MF3 would appear to have a low potential for soil erosion.
- MF1 has the highest potential for erosion due to soil conditions and the deep cut required for construction and soil conditions.
- MF2 has a slightly lower potential for erosion due to the reduced amount of cut and fill required over that of MF1.
- MF5 would likely have more foundation engineering design and construction issues than MF1, MF2, and MF3 because the soils that occur at this general area are prone to settlement.

4.11.4 Potential Mitigation Measures

During final design, additional geotechnical studies will inform and refine development of construction techniques and mitigation measures to avoid potential impacts and geologic risks during operations. Engineering design standards and BMPs would be used to avoid and minimize potential construction impacts. Based on the review of potential impacts, the design and construction process would address seismic hazards, soft soils, settlement, steep-slope hazards, landslide hazards, erosion and sediment control, vibrations, and groundwater.

4.12 Hazardous Materials

4.12.1 Introduction to Resources and Regulatory Requirements

This section discusses the potential for East Link Project alternatives to encounter hazardous materials that could pose risks to human health and the environment or that could create control or cleanup requirements for the project. This section also discusses the potential for alternatives to introduce new sources of hazardous materials contamination. This analysis has been performed in general accordance with American Society for Testing and Materials (ASTM) search radius guidance (ASTM E 1527), as referenced in the Washington State Department of Transportation's (WSDOT's) *Environmental Procedures Manual* M 31-11 (WSDOT, 2007).

Hazardous materials can be classified in a number of different categories based on laws and regulations that define their characteristics and use. These categories include hazardous waste, dangerous waste, hazardous substances, and toxic substances. Applicable laws and regulations include the following:

- Comprehensive Environmental Response Compensation and Liability Act (CERCLA) (42 U.S.C. 9601, *et seq*.)
- Superfund Amendment and Reauthorization Act (SARA)
- Resource Conservation and Recovery Act of 1976 (RCRA), as amended (42 U.S.C. 6901, *et seq*.)
- Clean Water Act (CWA) (33 U.S.C. Section 1 251, *et seq*.)
- Toxics Substances Control Act (TSCA) (15 U.S.C. 2601-2629)
- Dangerous Waste Regulations (Washington Administrative Code [WAC] 173-303)
- Model Toxics Control Act (MTCA) and its implementing regulations (RCW 70.105D and WAC 173-340)
- Underground Storage Tank Statute and its implementing regulations (RCW 90-76 and WAC 173-360)
- Sediment Management Standards (WAC 173-204)

Model Toxics Control Act Cleanup Regulation

The Model Toxics Control Act Cleanup Regulation, WAC 173-340, implements the Model Toxics Control Act (MTCA), RCW 70.105D, and sets forth strict requirements regarding site discovery and reporting, site assessments, and site remediation. Most importantly, the regulation defines standard methods used to assess whether a site is contaminated or clean.

Related resources and regulatory requirements are covered under historical and current land uses in the study area (Section 4.2), geologic conditions (Section 4.11), and groundwater conditions (Section 4.9).

4.12.2 Affected Environment

The study area for the hazardous materials analysis is the area within a 660-foot (approximately 1/8 mile) radius buffer surrounding each alternative. This study area was selected because if contamination is present, then the proximity of these sites could affect the project or the project could affect the site.

Sound Transit acquired information about sites with known contamination or potential contamination within the study area, as well as relevant historical conditions within the study area. Sound Transit collected information from multiple data sources, including the following:

- Environmental agency database records (Environmental Data Resources, Inc. [EDR], 2007)
- Washington State Department of Ecology (Ecology) Northwest Region Office site files
- Historical fire insurance maps (Sanborn maps) (King County GIS, 2009)
- Historical aerial photographs (King County GIS (2009)
- Online County Assessor data (KCGIS Center) (King County GIS, 2009)
- Current topographic and geologic maps (King County GIS, 2009)
- Windshield reconnaissance of the study area

Environmental agency records that were reviewed include those maintained by the U.S. Environmental Protection Agency (EPA) and Ecology. These databases track sites with potential or confirmed hazardous material releases to the environment and to monitor facilities that manage hazardous materials as part of their operations.

A search of these EPA and Ecology databases was conducted in February 2007 and again in October 2009 (EDR, 2007, 2009) to identify sites in or adjacent to the study area that have a record of hazardous material, substance, or waste handling, or that could be contaminated or have been contaminated in the past. The database search report identifies the locations of such sites and assigns an identification (ID) number to each site. The approximate locations of these sites are shown in the maps in Appendix G3. Appendix G3 also presents tabular information about these sites. Note that hazardous materials sites newly identified in the October 2009 database search are shown on the maps with the letter "N" added to the site ID to distinguish them from the 2007 database search (e.g., N198).

Based on all of information collected, sites were categorized into three risk categories: high, medium, and low. The purpose of this risk analysis was to prioritize sites to determine the need for avoidance, remediation, or mitigation while considering associated costs and liability. The risk levels are defined as follows:

- **High.** This risk level identifies sites that might be substantially contaminated and might create liability for Sound Transit either due to construction activities or by virtue of acquiring all or a portion of the site, such as for a maintenance facility. High-risk sites typically involve contaminants that are difficult to treat (e.g., perchloroethylene [PCE]), have large volumes of contaminated materials, or have long histories of industrial or commercial use.
- **Medium.** This risk level identifies sites where the nature of potential contamination is known based on existing investigation data, the potential contaminants are not extremely toxic or difficult to treat, and probable remediation approaches are straightforward. It typically involves sites located within or adjacent to project construction limits that have soil contaminated with petroleum products or nonadjacent sites that have groundwater contaminated with petroleum products.
- **Low.** This risk level identifies sites where the nature of potential contamination is known based on existing investigation data, and the sites are not expected to have noticeable impacts on the project due to their location. It typically involves sites that are not directly adjacent to the alternative right-of-way and do not have groundwater contamination.

Table 4.12-1 lists the number of sites and the risk categories identified within 660 feet of each segment and alternative. In addition to sites designated as high, medium, and low risk, there are also sites where the following has occurred:

- Hazardous materials have been used but where no previous releases have been reported.

TABLE 4.12-1
Number of Hazardous Material Sites within 660 Feet of Each Segment and Alternative[a]

Segment/Alternative[b]	High	Medium	Low
Segment A, Interstate 90	**0**	**29**	**16**
Preferred Alternative A1	0	29	16

TABLE 4.12-1 CONTINUED
Number of Hazardous Material Sites within 660 Feet of Each Segment and Alternative[a]

Segment/Alternative[b]	High	Medium	Low
Maintenance Facilities			
MF1	0	0	0
MF2	2	0	0
MF3	0	0	3
MF5	0 to 1	0	8 to 11

[a] The number of hazardous material sites for all risk levels should be considered as a snap shot in time because actual facility environmental conditions vary over time and environmental databases that are used are constantly being updated; therefore, sites can be added or deleted regularly. In addition, the number of medium- and low-risk sites should be considered as approximate because the site locations have been placed based on a single point and can fall inside or outside of the 1/8 mile (660 feet) buffer.

[b] The number of hazardous material sites for each alternative includes all possible connectors for that alternative.

[c] C9T – East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change in impacts for either *Preferred Alternative C9T* or *B2M*.

[d] Impacts for D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

- Sites were listed as having regulatory interactions not related to potential release of hazardous materials to the soil or groundwater (i.e. permitted air emissions).
- The sites have had a small one-time spill (i.e. less than 10 gallons) event that is reported to be cleaned up.

These sites are considered as minimal risk sites and are listed in Appendix G3 as Risk Level 4 sites.

4.12.3 Environmental Impacts

This section discusses the potential impacts that the project might have on the environment and potential impacts that the known and suspected contaminated sites might have on project development and Sound Transit liability. Operational impacts and construction impacts are considered. Sound Transit will meet regulatory requirements associated with construction and operation of the East Link Project.

4.12.3.1 No Build Alternative

With the No Build Alternative, removal or cleanup of potentially hazardous materials in the study area, including contaminated soil or groundwater, would not be removed or cleaned up, and the potential uncontrolled migration of existing contaminants might continue.

What is PCE?

PCE, or perchloroethylene, is a manmade chemical used for dry-cleaning clothes, degreasing metal parts, and as an ingredient in the manufacturing of other chemicals.

PCE contamination in soil might be cleaned up by excavating the soil, incinerating it, and disposing of the ash in a landfill.

PCE can also be treated in place using a method known as **soil vapor extraction**. Soil vapor extraction uses a network of perforated pipes placed in the soil to remove PCE vapor from the pore spaces in soil and pass it through activated carbon where it can be captured and eventually destroyed.

The particular method used to clean up PCE contamination in soil depends upon conditions such as PCE concentration, access to contaminated soil, cost of soil disposal, and other site-specific factors.

4.12.3.2 Impacts during Operation

Most impacts associated with encountering sites with existing contamination would occur during construction (as discussed in Section 4.12.3.3). However, long-term operational impacts could occur when Sound Transit acquires properties that are the source of contamination and, therefore, could require an ongoing cleanup responsibility. Such sites are typically associated with groundwater contamination or are large and complex. The actual operational impacts at such hazardous materials sites cannot be identified or assessed without evaluating in detail site-specific conditions, which would be performed before, during, or after construction.

Impacts during normal operation are unlikely since the trains operate through electricity; therefore, fuel spills would not occur. However, minor impacts during operation could result from using hazardous materials during maintenance activities on the tracks and at the maintenance facility to be located in either Segment D or E. During track maintenance, there would be an extremely low chance that a small amount of diesel fuel or hydraulic fluid could spill from the maintenance vehicles. Activities at the maintenance facilities would involve using hazardous materials, including lubricants, solvents, and other chemicals. In addition, hazardous waste (e.g., petroleum products and waste solvents) would be generated. Hazardous waste generated at the maintenance facilities would be managed according to applicable regulatory requirements, which minimize the exposure risk. In addition, the facilities would be constructed with engineering controls to limit and contain releases and spills. The likelihood of impacts (i.e., releases) from project operation and maintenance activities would be low.

Preferred Alternatives

With the *Preferred Alternatives*, long-term operational impacts could occur at the following three high-risk sites if Sound Transit acquires these properties:

- Bellefield Office Park (Site 352) would be partially acquired for *Preferred Alternative B2M*, as well as for Alternative B2E and Alternative B3, both with and without the B3 - 114th Extension Design Option.
- Safeway Warehouse Distribution Center (Site 221C) would be partially acquired for *Preferred Alternative D2A.* Other alternatives that might impact this site are Alternatives D2E and D3.
- King County Materials Lab/City of Redmond Site (Site 38) would be acquired for *Preferred Alternative E2.* Also all segment E alternatives would impact this site.

The Bellefield Office Park (Site 352) was developed in the 1970s using imported fill reported to be demolition wood debris from wood frame residences that were demolished for I-405 construction. Contaminated soil and groundwater were encountered within the Bellefield Office Park, and the contaminants included total petroleum hydrocarbons (TPHs), polychlorinated biphenyls (PCBs), and polynuclear aromatic hydrocarbons (PAHs). A Restrictive Covenant has been in place for this site since 1996; this Restrictive Covenant prohibits activities that would release contaminants at the site without Ecology's approval and prohibits any use of the property that is inconsistent with the Covenant (Ecology, 2009). The Safeway Warehouse Distribution Center (Site 221C) has had petroleum product release from underground storage tanks (USTs). The releases have reportedly been cleaned up, but there might be residual contamination. The King County Materials Lab/City of Redmond Site (Site 38) has confirmed and suspected presence of chlorinated organic compounds (e.g., PCE) in groundwater and soil; therefore, ongoing cleanup might be required.

Property acquisition by Sound Transit could include the former BNSF Railway corridor, which is identified as a high- risk site. Depending on the alternative selected, the project might run within, parallel to, or cross over the former BNSF Railway corridor. However, operational impacts due to acquiring the former BNSF Railway corridor are not expected.

Other Alternatives

For Alternative B7, two sites would be acquired: Eastside Disposal (Site 343A) and Sound Oil Company/Davey Tree (Site 343C) sites.

Site 343A is currently operated by Eastside Disposal, and Allied Waste uses it to store equipment. The soils on the site were contaminated with petroleum products from a leaking UST.

Site 343C was formerly occupied by Sound Oil Company and is now occupied by Davey Tree Service. Sound Oil Company had three USTs containing diesel and stove oil removed in August 1990. Residual petroleum contamination could still be present.

No other sites with potential operational impacts were identified during the regulatory databases review.

4.12.3.3 Impacts during Construction

Potential construction impacts could result from encountering existing soil or groundwater contamination and from encountering containers holding hazardous materials. Soil or groundwater contamination could be found on or adjacent to contaminated sites and in utility corridors, which can be conduits for contamination. Containers that hold hazardous materials include above- and underground storage tanks, which typically contain petroleum products, and pole-mounted electrical transformers, which might contain PCB-contaminated transformer oil. The likelihood of impacts from encountering existing contamination or hazardous materials containers depends upon the extent and characteristics of the contamination and hazardous materials. A variety of impacts, both beneficial and adverse, would be possible, including the following:

- Construction activities, such as grading, in the vicinity of these materials could release contaminants to soil, groundwater, and surface water.
- Contaminated materials might be uncovered, allowing more direct exposure to the public.
- Contamination might spread as a result of construction.
- Dewatering that might occur to further construction activities might generate large quantities of contaminated water that would need to be treated and disposed of.
- Contamination that otherwise would remain in place and potentially migrate might be discovered and addressed by the project.
- To accommodate project construction, contamination might be cleaned up earlier than otherwise would occur.
- Contamination might be prevented by removing potential existing sources, such as USTs and

aboveground storage tanks (ASTs), before they cause releases.

Demolishing, removing, and disposing of existing structures during planned construction could release hazardous materials. Asbestos (commonly used in construction because of its insulation, fireproofing, and soundproofing qualities) causes cancer and other respiratory problems; asbestos is most dangerous when crushed, broken, or otherwise disturbed so that fibers are released to the air and inhaled. Lead is often found in lead pipes, copper pipes with lead solder, and interior and exterior painted wood, siding, window frames, and plaster and could cause lead poisoning if handled inappropriately and inhaled or ingested during demolition.

Contaminated material requiring special disposal—such as old railroad ties and contaminated soil—could also be generated from construction activities within and along railway corridors and crossings. Some historical railroad operations used chemicals that might have resulted in soil contamination. The most commonly reported contamination along rail lines includes metals, pesticides, and constituents of oil or fuel (petroleum products). These chemicals have been associated with normal railroad operations and would likely be found anywhere along the line. For example, arsenic (up to ten times natural background levels) is commonly present in the soil along a railroad right-of-way as a result of old railroad ties dipped in an arsenic solution, arsenic weed-control sprays, and arsenic-laced slag used as railroad bed fill. Lubricating oil and diesel that dripped from the trains would be likely sources of the petroleum product found along the lines. Other sources of contaminants associated with historical railroad operation might include coal ash from engines, creosote from ties, and PAHs from the diesel exhaust.

Potential construction impacts could result from accidental release of hazardous substances (such as lubricants and fuels needed for heavy equipment), a hazard common to all construction projects but particularly acute for construction over water or in areas where stormwater runs off into water bodies such as Lake Washington. Spills of any size, if not contained, could harm water quality, vegetation, and wildlife in the immediate area and downstream; large spills could require emergency response.

Measures Sound Transit would use to minimize the potential for accidental release of hazardous substances during construction include the following:

- Assess sites where contamination might be present to identify the presence and extent of any contaminants. Sites where stormwater facilities are proposed are especially important to survey because any contaminants exposed there could be carried offsite when the stormwater is discharged.
- Locate ASTs, USTs, and fuel lines before construction to reduce the potential for breakage and spills.
- Survey structures that would be demolished to determine whether they contain hazardous building materials such as asbestos, lead-based paint, and PCBs.
- Specify construction techniques that minimize disturbance to areas where contamination might exist, and phase construction activities to follow cleanup activities whenever possible.
- Prepare a comprehensive contingency and hazardous substance management plan and a worker health and safety plan to reduce potential risks to human health.
- Prepare a spill prevention, control, and countermeasure plan and a stormwater pollution prevention plan to manage and prevent the release of pollution and hazardous substances to the environment.

The following subsections describe the potential impacts on the project from known contaminated sites based on their location relative to the proposed alternatives. The focus of the discussion is on high-risk sites because these are the sites that are anticipated to have the greatest impact on project development. Some of these sites could also have long-term impacts if they involve continuing cleanup responsibilities (e.g., groundwater monitoring) even after the project is constructed. The actual impacts on the environment at each hazardous materials site cannot be identified and assessed without detailed evaluations of site-specific conditions, which would be performed prior to or during construction. Site assessment might be conducted in a phased approach to address cost, schedule, and technical requirements associated with the construction process. Details about these high-risk sites are discussed under each segment.

Railroad corridors or crossings occur under *Preferred Alternatives C11A*, *C9T*, *D2A*, and *E2*; Maintenance Facility MF2; and various other alternatives within Segments C, D, and E. Impacted parcels would be acquired by Sound Transit; permanent easements might also be obtained. Construction impacts, such as encountering contaminated soil, as discussed above, should be anticipated everywhere along the railroad corridors and crossings and are not discussed separately under individual segments. For this section, railroad corridors and crossings, referred to as former BNSF Railway corridor throughout this section, are considered as one high-risk site under each segment regardless of how many individual parcels are involved.

Segment A

There are no high-risk sites, 29 medium-risk sites, and 16 low-risk sites within the study area for Segment A. Segment A begins at the Downtown Seattle Transit Tunnel (where the East Link Project would connect to the Central Link light rail system) and extends to South Bellevue where I–90 touches land in Bellevue. All Segment A construction is proposed to occur within the existing I-90 right-of-way and would involve minimal ground-disturbing activities, such as soil excavation or construction dewatering. Therefore, any contamination that might exist or that has migrated from hazardous material sites within the Segment A study area are not expected to affect project construction.

Segment B

There are seven high-risk, four medium-risk, and six low-risk hazardous material sites within the Segment B study area. Table 4.12-2 summarizes the potential impacts related to high-risk sites, and Exhibit 4.12-1 shows their location relative to each alternative. The former BNSF Railway corridor, also a high-risk site, is not shown on Exhibit 4.12-1. There are two high- and one medium-risk sites along *Preferred Alternative B2M.* In addition, two low-risk sites are located in this alternative.

Site 352 is located on the east side of 112th Avenue SE between SE 8th Street and the Mercer Slough. The Bellefield Office Park was developed using imported fill material reportedly resulting from demolition debris largely consisting of wood wastes from residential construction. Contaminants detected in soil and groundwater at the site include petroleum products, PCBs, and PAHs (Ecology, 2009).

Site N198 is located on SE 8th Street between 112th Avenue SE and Lake Washington Boulevard. The fill material beneath SE 8th Street is believed to be of the same origin as that beneath the Bellefield Office Park (Site 352) (PanGeo, 2000). As part of the SE 8th Street roadway improvement project conducted by the City of Bellevue, soil and groundwater samples were collected; these samples confirmed the presence of petroleum contaminated soil and groundwater in the subgrade soils beneath the roadway (Agra Earth, 2000 and G-Logic, 2003).

Alternatives B2A, B2E, and B3 (with and without B3 - 114th Extension Design Option) could be impacted by the same high-risk sites as *Preferred Alternative B2M.* Alternatives B1 and B7 could be impacted by two and three high-risk sites, respectively.

Site 412A is located adjacent to the at-grade rail profile of Alternative B1, and it has been used as a dry-cleaning business since at least the 1960s; the site is currently occupied by Enatai Cleaners. Soil gas probing and groundwater monitoring investigations indicated that PCE is present in the soil gas and in the groundwater in excess of MTCA Method A cleanup level (Dalton, 1994).

Site 412B is also located adjacent to the at-grade profile of Alternative B1. The site currently operates as a gas station and is hydraulically downgradient from the Kevik Cleaners site (Site 412A). The soils on the site were contaminated with petroleum products from leaking USTs. Soil excavation was conducted in 1992. Petroleum-impacted soil remains in place below the embankment on the east side of the site, adjacent to and below the area of the former heating oil tank excavations. In addition, soil and groundwater at the site have been reported to contain PCE in excess of MTCA Method A cleanup levels (EMCON, 1994a). The former dry cleaners located upgradient of the site is suspected to be the source of the PCE. (EMCON, 1994b).

Site 343A would be acquired to construct the park-and-ride lot and 118th Station for Alternative B7. Eastside Disposal currently operates on the site, and Allied Waste uses it to store equipment. The soils on the site were contaminated with petroleum products from a leaking UST. The soil was excavated until field-screening methods indicated no presence of petroleum hydrocarbons. However, confirmation soil samples indicate that ethylbenzene, diesel, and possibly heavier oil concentrations exceeding MTCA Method A cleanup levels still exist in the soil underneath the welding shop. The contaminated soil near the welding shop footprint was not remediated due to engineering constraints (Hart Crowser, 1990).

Site 343C also would be acquired to construct the park-and-ride lot and 118th Station proposed under Alternative B7. This site was formerly occupied by Sound Oil Company and is now occupied by Davey Tree Service. Sound Oil Company had three USTs containing diesel and stove oil removed in August 1990, and soil was excavated when bioremediation failed at the site (Marsh, 1996). Contamination is reported to be below MTCA Method A cleanup levels (Ecology, 2004). Ecology lists the site status as “reported cleanup” without a detailed review. This site is considered as a high-risk site because residual petroleum contamination could still be present and the site could be acquired by Sound Transit.

N/A	not applicable
PAH	polyaromatic hydrocarbon
PCB	polychlorinated biphenyl
PCE	perchloroethylene

Former BNSF Railway corridor along the east side of Mercer Slough would also be leased or acquired under the Alternative B7. Contaminated material requiring special disposal—such as old railroad ties and soil contaminated with petroleum products, PAHs, pesticides, and metals—could be present within and along the railway corridor.

Segment C

There are 8 high-risk, 28 medium-risk, and 19 low-risk hazardous material sites within the Segment C study area. The connectors from Segment B do not change the number of affected high-risk sites in Segment C. Table 4.12-3 summarizes the potential impacts, and Exhibit 4.12-1 shows the location relative to each alternative. The former BNSF Railway corridor, also a high-risk site, is not shown on Exhibit 4.12-1.

Preferred Alternative C11A has 2 high-risk sites; in addition, this alternative includes 19 medium-risk sites and 12 low-risk sites.

Site 306C is adjacent to *Preferred Alternative C11A*. The site was formerly used by a dry cleaner, and a remedial investigation found PCE in a downgradient storm sewer manhole. From 1996 to 2000, a soil vapor extraction system (a device that applies a vacuum to remove airborne chemicals) was used to reduce the PCE concentration in the soil. All soil near the storm sewer manhole containing PCE concentrations greater than Method B cleanup levels were removed (Floyd Snider McCarthy, 2003). According to Ecology, groundwater is believed to be affected by the historical PCE releases (EDR, 2009).

[a] With and without C9T – East Main Station Design Option

N/A	not applicable
PCE	perchloroethylene

Any construction in this area could expose potentially contaminated soil and groundwater.

Former BNSF Railway corridor between NE 6th and NE 12th Streets would be leased or acquired. Contaminated material requiring special disposal, such as old railroad ties and soil contaminated with petroleum products, PAHs, pesticides, and metals, could be present within and along the railway corridor.

Preferred Alternative C9T has 2 high-risk (Site 306C, and former BNSF Railway corridor), 17 medium-risk, and 6 low-risk sites. These high-risk sites are discussed above under *Preferred Alternative C11A*.

All other Segment C alternatives have high-risk sites, especially Alternative C1T, which has 7 high-risk, 20 medium-risk, and 13 low-risk sites along the route. Compared with *Preferred Alternative C9T* and all the other alternatives, Alternative C1T would have the greatest risks because of the number of high-risk sites and the nature and extent of potential contamination. For example, PCE is believed to be present in the soil or groundwater at Sites 294C, 301B, 305B, and 304D, which are located along Bellevue Way between NE 4th Street and Main Street (see site descriptions below). In addition to the former BNSF Railway corridor discussed under the *Preferred Alternative C11A* above, the other six high-risk sites are discussed below.

Site 263C is located one block north of the tunnel for Alternatives C1T and C2T and one block west of the tunnel for Alternative C3T and the southbound alignment for Alternative C4A. In the past, the site was used as a gasoline station and dry cleaner. Soil and groundwater were reportedly impacted by a PCE release at a depth between 7 and 18 feet below ground surface (bgs) at the center of the property (Golder Associates, 2004). A shallow groundwater aquifer is located at 14 to 18 feet bgs, and it is not known whether the site's perched groundwater has impacted the deeper regional aquifer.

Site 294C is located adjacent to the tunnel for the Bellevue Way Tunnel (C1T). It was home to a dry-cleaning operation from 1951 to 1962. In the 1960s, the operation moved to an adjacent building. PCE has been detected in the groundwater (Hart Crowser, 2001, 2005). The plume of PCE extends to the south and southeast, south of the 315 Bellevue Way NE to beyond NE 2nd Street.

Site 301B is located adjacent to the tunnel for Alternative C1T. The site has been home to a variety of dry-cleaning establishments since the 1970s, and site investigations have found PCE in the soil and groundwater (Hart Crowser, 1997). Sampling conducted in 1998 further confirmed the presence of PCE in the groundwater (Hart Crowser, 1999). The site is listed as awaiting remedial action.

Site 304B is located one block west of the tunnel for Alternative C1T. The site operated as a dry-cleaning business from the 1950s through the late 1980s. Investigations conducted in 2006 confirmed the presence of petroleum product, petroleum product-related volatile organic compounds (VOCs), and PCE in the soil and groundwater (PES Environmental, 2006). The suspected sources of the petroleum and related VOC contamination include the Unocal property (Site 305B, described below) located to the north. The suspected source of PCE and related chlorinated organic compounds, such as trichloroethylene and vinyl chloride contamination, is the dry cleaners formerly located on Site 304B. There is an east to southeast groundwater flow direction across most of the site.

Site 304D is located one block west of the tunnel for Alternative C1T; Ecology has no information available for this site. The EDR report indicated that the final *Independent Remedial Action Report* has been received. This site is considered to be high-risk because of its location adjacent to the tunnel route and a high level of uncertainty due to lack of information. This site is possibly linked to the petroleum product and PCE releases from nearby sources.

Site 305B, the Unocal property, is located adjacent to the tunnel for Alternative C1T. In the past, the site was used by a gas station. Investigations revealed gasoline product in the groundwater beneath the southern part of the site (Maul, 2003). A groundwater recovery/treatment system and vapor extraction system were installed in 1991 to remediate the groundwater and soil. Chlorinated solvents were detected in the groundwater within the site and its immediate vicinity, particularly to the south (ENSR, 2006).

Alternative C2T has three high-risk sites (Sites 263C, 306C, and the former BNSF Railway corridor), Alternative C3T and C4A each have two high-risk sites (Sites 263C, and 306C), Alternatives C7E and C8E have no high-risk sites, Alternative C9A has two high-risk sites (Sites 306C and former BNSF Railway corridor), and Alternative C14E has one high-risk site (former BNSF Railway corridor).

Segment D

There are 6 high-risk, 25 medium-risk, and 12 low-risk hazardous material sites within the Segment D study area. The number of sites do not differ between the connection points from Segment C, except that the connection from NE 12th Street would eliminate the interaction with the former BNSF Railway corridor site in Segment D. All Segment D alternatives potentially would be impacted from two or more of the sites. Table 4.12-4 summarizes the potential impacts, and Exhibit 4.12-2 shows locations of the high-risk sites relative to each alternative. The former BNSF Railway corridor, also a high-risk site, is not shown on Exhibit 4.12-2.

Depending on the Overlake Village Station design option selected, the *Preferred Alternative D2A* would be affected by two high-risk sites when the preferred alignment continues adjacent to SR 520 (avoiding Site 146C), or three sites if the NE 24th Design Option is selected.

Site 221C, the former Safeway Warehouse Distribution Center, would be partially acquired for the at-grade profile and stations of *Preferred Alternative D2A*. The 3.5-acre site was formerly used by Safeway as a warehouse and distribution center. The five-building complex includes a retail and warehouse building, cross dock, cold storage, office building, and a former vehicle maintenance shop; the complex is currently vacant. The site has had as many as 20 USTs at one time or another, and leaking USTs were reported in 1995, 1998, and 2001. These leaking USTs were removed, and remedial actions for petroleum-contaminated soil were conducted. In April 2009, Ecology issued a “No Further Action” determination for the site, based on review of submitted documents. This site is of high concern because of the scale of the past operations and its location at a light rail station, which leads to a high likelihood of encountering contamination. During development, previously undiscovered contaminated soil might be encountered within the Safeway warehouse site due to historical releases from these USTs.

Site 146C is located approximately one block south of D2A - NE 24th Design Option alignment. This site has been home to a variety of dry cleaners since 1977. In 2000, PCE was identified in the soil and groundwater, and in November 2004, a soil vapor extraction system began operating to remove the contamination from the soil. Monitoring from September 2004 to October 2005 showed that contaminants still exceed groundwater standards (SCS Engineers, 2006).

Former BNSF Railway corridor north of NE 12th and NE 6th Streets and within the Safeway Warehouse Distribution Center parcel would be leased or acquired. Contaminated material requiring special disposal, such as old railroad ties and soil contaminated with petroleum products, PAHs, pesticides, and metals, could be present within and along the railway corridor. This is also true for the preferred storage track location located in the former BNSF Railway corridor just north of the proposed Hospital Station. All Segment D alternatives could potentially be affected by the former BNSF Railway corridor, a high-risk site, since they would all interact with the former rail corridor. The potential impact would be greater if the preferred location for an interim terminus is selected since this would include storage tracks in the former BNSF Railway corridor.

All Segment D alternatives, except Alternative D5, could potentially be impacted by Site 221C. In addition, Alternative D2E could potentially be impacted by Sites 146C described previously, Alternative D3 could be impacted by Sites 176C and 188, and Alternative D5 could be impacted by Site 174B. Sites 174B, 176C and 188 are described below.

Site 174B is located within the Alternative D5 alignment. Weyerhaeuser currently uses the site as a manufacturing facility for corrugated containers. The site was occupied by Willamette Industries and used as a forest product manufacturing facility prior to being purchased by Weyerhaeuser in 2002. Petroleum contamination was reportedly cleaned up as of 2002.

Site 176C is located one block east of the retained-cut profile of Alternative D3, and it is currently used by a dry-cleaning business and was formerly used as a gas station. Contaminants of concern, released from these two businesses, include chlorinated solvents and petroleum hydrocarbon. Cleanup activities have been ongoing since 2004 and include soil vapor extraction and air sparging (pumping air underground to aid removal of chemical vapors).

Site 188 is located adjacent to the retained-cut profile of Alternative D3. This site was formerly occupied by a retail gas station, and it is currently occupied by restaurants. Investigations conducted in the early 1990s found benzene concentrations in excess of MTCA Method A cleanup levels in the soil. In 1993, four gasoline USTs were removed, and soil vapor extraction and groundwater air sparging began. In June 2000, soil borings showed no petroleum hydrocarbons exceeding MTCA Method A cleanup levels (Environmental Resolutions, Inc., 2006a). According to a 2006 groundwater monitoring report, three of nine wells sampled contained benzene concentrations in excess of MTCA Method A cleanup levels (Environmental Resolutions, Inc., 2006b).

Segment E

There are 6 high-risk, 11 medium-risk, and 9 low-risk hazardous material sites located within the Segment E study area. Table 4.12-5 summarizes the potential impacts, Exhibit 4.12-2 shows locations of the high-risk sites relative to each alternative. The former BNSF Railway corridor, also a high-risk site, is not shown on Exhibit 4.12-2.

Site 27 is adjacent to the terminus of *Preferred Alternative E2* and is currently used by a dry-cleaning business. Ecology determined that a release of PCE to soil and groundwater from the site represented a significant threat to human health and the environment (Ecology, 1999). Environmental remedial actions conducted at the site included soil vapor extraction and groundwater monitoring (Ecology, 2002). Remedial action is listed as in progress as of February 2008.

Site 38 is adjacent to the at-grade profile of the *Preferred Alternative E2*. The King County Department of Transportation Road Services Division, Materials Laboratory and Surveyors, Animal Control, Office of Civil Defense, Sheriff's Department, and the City of Redmond have all occupied portions of the property at 7733 Leary way NE, Redmond. A subsurface investigation of the site was conducted in 2002, and soil and groundwater samples indicated that TPH as diesel-range organics (DRO) and oil-range organics (ORO), as well as PCE, are present at levels exceeding their applicable cleanup levels (City of Redmond, 2004). A "No Further Action" letter was issued by Ecology for Leary Way Shop Site Buildings 1 through 9; however, this site is also listed in Ecology's list of contaminated sites under the City of Redmond for confirmed presence of chlorinated organic compounds in groundwater, suspected presence of chlorinated organic compounds in soil, and confirmed presence of petroleum products in soil. The City of Redmond site status is listed as "Awaiting Cleanup" as of June 2009.

Site 59A is located adjacent to the at-grade profile *Preferred Alternative E2*. The site is currently used by a large industrial painting contractor that handles solvents and solvent-based paints; also, gasoline USTs are on the site. During an investigation, petroleum products were observed on the ground near the fuel pump area.

N/A	not applicable
PAH	polyaromatic hydrocarbon
PCE	perchloroethylene

This area was cleaned up in 1992 when two USTs were removed. In 1994, a site hazard assessment was conducted and the soil samples were reportedly below MTCA cleanup levels. Ecology issued a “No Further Action” determination for the site in 1995 (Seattle-King County Department of Public Health, 1995). However, contamination such as petroleum products, metals, and chlorinated or nonchlorinated organic compounds that were used as solvents might still exist at the site in lower levels.

Site 112 is next to the retained-cut profile of all Segment E alternatives. The site was formerly used by Fort James Corporation as a paper product manufacturing facility; the site is currently occupied by Microsoft Corporation. Petroleum products and chlorinated organic compounds have been detected in soil and groundwater at the site. The site is in Ecology’s Voluntary Cleanup Program and cleanup is ongoing as of 2010.

Site N22 is located adjacent to *Preferred Alternative E2*, and it was occupied by T&D Feeds from the 1930s to 2000. T&D Feeds used the site as a store, feed mill, and warehouse complex (Redmond Historical Society, 2011. The structures were demolished in 2001, and the site is currently vacant. Soil at the site was contaminated with petroleum products and carcinogenic PAHs. A remedial action was conducted on the property and resulted in a “No Further Action” determination from Ecology in 2006 for soils at the site. PCE-contaminated groundwater was also detected at the site; however, Ecology has determined that the PCE appeared to be from an offsite location, and therefore, no further action was required by Ecology. The 2006 “No Further Action” letter also noted that an adjacent railroad property to the southeast of the T&D Feeds property contains carcinogenic PAHs in soil that will require further remediation (Ecology, 2006).

Former BNSF Railway corridor is encountered at several locations in all of the Segment E alternatives. Contaminated material requiring special disposal, such as old railroad ties and soil contaminated with petroleum products, PAHs, pesticides, and metals, could be present within and along the railway corridor.

E2 - Redmond Transit Center Design Option would be impacted by the same sites as *Preferred Alternative E2* described above except for Site 27. Alternatives E4 would have four high-risk sites (Sites 38, 112, N22, and the former BNSF Railway corridor), and Alternative E1 would have the same four high-risk sites plus Site 27.

Site 59A, which impacts *Preferred Alternative E2* and is described above, appears to be south of Alternative E1 and would not appear to impact it. Alternative E4 could be impacted by four hazardous materials sites (Sites 38, 112, N22, and former BNSF Railway corridor); these sites are in areas where the alternatives overlap. Alternative E4 avoids Sites 27 and 59A.

Maintenance Facilities

As with constructing any portion of East Link, potential construction impacts from maintenance facilities could result from using hazardous materials, (e.g., lubricants, fuels, and solvents) during construction or from encountering sites with existing soil or groundwater contamination. The potential for encountering hazardous material during construction of the maintenance facilities is relative to the number of businesses associated with hazardous materials that would be displaced and the extent of excavation that might be required during facility construction.

There are 3 high-risk, 0 medium-risk, and 11 low-risk hazardous material sites for the maintenance facilities. Table 4.12-6 lists the potential impacts related to high-risk sites for each maintenance facility and Exhibit 4.12-2 shows their location. The 116th Maintenance Facility (MF1) and the SR 520 Maintenance Facility (MF3) would not acquire any known sites.

Site 174B, previously discussed under Segment D, and former BNSF Railway corridor, would be acquired as part of the BNSF Maintenance Facility (MF2).

Site 59A, previously discussed under Segment E, would be acquired as part of the SE Redmond Maintenance Facility (MF5).

4.12.4 Potential Mitigation Measures

In order to mitigate potential impacts from all potential sites, including railroad corridors and crossings, Sound Transit would perform a level of environmental due diligence appropriate to the size and presumed past use of the property at all properties along the corridor before they are acquired. Phase 2 Environmental Site Assessments would be conducted where appropriate. Where known hazardous sites are present, Sound Transit would be responsible for the remediation of any contaminated soil and groundwater, including that which would be previously unknown and found during construction. To the extent practical, Sound Transit would limit construction activities that might encounter contaminated groundwater or contaminated soil.

4.13 Electromagnetic Fields

4.13.1 Introduction to Resources and Regulatory Requirements

Electric and magnetic fields, known as electromagnetic fields (EMFs), are produced wherever electricity is used. Electric fields are produced by charges. Magnetic fields are produced by the flow of electric current. The greater the electric charge, the greater the electric field. Similarly, the greater the electric current, the greater the magnetic field. EMFs surround all electrical equipment and facilities, including the electrical conveyance lines and electrical devices as proposed in the East Link Project. Although there are no regulatory requirements for EMF, EMF results in electromagnetic interference (EMI), which can cause disruptions and possibly malfunctions in sensitive equipment. In certain situations with sufficiently high exposure, EMF can result in effects on human health. The EMF study area is dependent on the location of sensitive equipment in relation to the light rail line and the amount of electrical power that the East Link Project requires to accelerate or decelerate near sensitive facilities. However, the potential for a light rail vehicle to adversely affect sensitive equipment from a distance greater than 100 feet is rare.

Where there are electric currents, it is possible that stray currents would occur when a portion of the electrical current finds an alternative conducting path, such as metal, water, or a buried pipe or cable. Over time, a stray current can cause corrosion, which in turn can cause pipes to leak or wires to break.

4.13.2 Affected Environment

The affected environment of the East Link system is the area immediately adjacent to project alternatives and on board the train cars. EMI may temporarily interfere with the operation of sensitive electronics and electrical equipment near the right-of-way, so the concern is for facilities that may be sensitive to EMI, such as hospitals or laboratories that use sensitive electronic equipment. Also, the pipes and cable utilities commonly located under and along roadways, including the floating bridge on I-90, can be susceptible to stray currents, which can be conducted some distance away from the right-of-way.

Sound Transit contacted Children's Hospital Bellevue Clinic and Surgery Center (BCSC), Overlake Hospital, and Group Health, all three of which have facilities near I-405, to identify sensitive receptors. As a result of these discussions, Sound Transit identified three buildings—Overlake's portable magnetic resonance imaging (MRI) unit, the Overlake outpatient optical surgery unit, and the MRI unit at Children's Hospital BCSC—as possibly being susceptible to EMI.

The Overlake portable MRI unit is a parked, trailer-mounted MRI unit located at the west end of the North parking garage at a loading dock shipping and receiving area next to several trash dumpsters and an electrical transformer that provides power to buildings on the hospital campus. This portable MRI unit operates next to large, energized electrical equipment and near roadways and parking garages with moving cars and trucks that produce magnetic fields.

The Overlake outpatient optical surgery unit is located just southeast of the NE 12th Street Overpass east of I-405 in the ground floor of Overlake's west garage.

The Children's Hospital BCSC has an MRI unit located in a magnetically shielded room on the second floor of the building. The MRI in the BCSC is located approximately 75 feet south of the south fence of the 116th Maintenance Facility (MF1) and approximately 240 feet north of where the 108th NE Tunnel (C3T), Couplet (C4A), 112th Elevated (C7E), and 110th Elevated (C8E) Alternatives would cross 116th Avenue NE at approximately NE 15th Street, east of I-405. Similar to the MRI unit at Overlake Hospital, the Children's MRI unit is located close to moving cars because it is in a room immediately above the ground-level parking garage beneath the BCSC.

The MRI in the BCSC is also located about 315 feet northwest of a Puget Sound Energy 115-kilovolt (kV) electrical substation. The substation does not produce EMF outside of the substation fence, but the overhead transmission lines that feed the substation and those that run along the east side of 116th Avenue NE presently produce modest levels of EMF (within the lower end of the range of the values reported in Table 4.13-1).

The BCSC MRI is located about 260 feet north of the overhead 115-kV transmission line that serves the substation and about 130 feet east of the transmission line that runs along the east side of 116th Avenue NE next to the BCSC. An earlier report (LTK Engineering Services, 2006) describes extensive measurements and magnetic field modeling performed for the Sound Transit North Link line near the University of Washington campus. In that report, LTK Engineering evaluated the magnetic fields that could be produced by operation of trains on the North Link line as well by as cars, large trucks, and buses that pass close to several of the campus buildings. Because the North Link and East Link light rail lines are similar and part of the Sound Transit light rail system, the model predictions and measurements described in the LTK Engineering report can also be used to predict the present and future magnetic field environment for the portable MRI unit and the Overlake outpatient optical surgery unit at Overlake Hospital as well as the MRI unit at Children's Hospital BCSC.

TABLE 4.13-1
Estimated External Magnetic Fields Near Children's Hospital Bellevue Clinic and Surgery Center Magnetic Resonance Imaging (MRI) Unit

Source of EMF	Distance from MRI Unit	Estimated Total Peak Magnetic Field [a]
Buses and large trucks moving in northbound lanes of 116th Ave NE	160 feet (46 meters)	0.1 milliGauss
Cars moving in ground level parking garage beneath BCSC	10 feet (3 meters)	20 milliGauss
Cars and trucks on driveway near south entrance to BCSC	135 feet (46 meters)	0.1 milliGauss
Cars moving on north driveway to ground level parking garage	33 feet (10 meters)	<1 milliGauss

[a] Estimates taken from measurements and modeling described in the LTK Engineering Services report (2006).

There are several external periodic magnetic fields located near the BCSC MRI unit, as described in Table 4.13-1. Since the BCSC is a new facility specifically designed for this location, it is not thought that these sources of EMF will cause any malfunctions for the MRI unit.

Similarly, there are several different external periodic magnetic fields located near the Overlake portable MRI unit, as described in Table 4.13-2.

These EMFs result from the perturbations of the earth's magnetic field that are caused by the movement of large metal objects such as cars, trucks, and buses. At present, the EMFs have not caused any malfunctions of the portable MRI unit.

It is likely that there are underground pipe and electrical and telephone cable utility lines along the segment alternatives, especially on I-90 and in Downtown Bellevue, that could be subject to stray currents. Accordingly, these utility lines would need to be carefully evaluated for the possibility of effects from stray currents and the need for protection from stray currents.

TABLE 4.13-2
Estimated External Magnetic Fields Near Overlake Portable Center Magnetic Resonance Imaging (MRI) Unit

Source of EMF	Distance from MRI Unit	Estimated Total Peak Magnetic Field [a]
Buses and large trucks moving in eastbound lanes of NE 12th Street	125 feet (38 meters)	0.1 milliGauss
Cars moving on driveway between West and North Parking Garages	16 feet (5 meters)	5 milliGauss
Large trucks on driveway between West and North Parking Garages	16 feet (5 meters)	10 milliGauss
Cars moving in North Parking Garage	33 feet (10 meters)	<1 milliGauss

[a] Estimates taken from measurements and modeling described in the LTK Engineering Services report (2006).

4.13.3 Environmental Impacts

4.13.3.1 No Build Alternative

The No Build Alternative would not introduce any new sources of EMI into the study area.

4.13.3.2 Impacts during Operation

Electromagnetic Fields

The overhead catenary wires and the power transmission lines that provide power to the traction power substations along the route would produce EMFs. EMFs would also be produced by the train cars themselves, both within and outside the cars, especially when they are moving. The electricity needed to operate the train cars flows from the overhead catenary wires to the traction motors and other electronic equipment. The power flows through cables located either in the ceiling or under the floor of the cars. The amount of electricity flowing in these cables would vary depending on whether the train is accelerating, running at steady speed, decelerating, or is stopped. The electrical current would be highest when the train is accelerating. EMFs would be created whenever the train operates.

Preferred 108th NE At-Grade Alternative (C11A) and *Preferred 110th NE Tunnel Alternative (C9T)* are not located close to any potentially EMF-sensitive sites. Only Alternatives C3T, C4A, C7E, and C8E approach the potentially EMF-sensitive sites. During interviews with staff of Overlake Hospital, Group Health, and Children's Hospital BCSC and personal visits to the Overlake portable MRI unit, the Overlake outpatient optical surgery unit, and the Children's Hospital BCSC MRI unit, the MRI units were the only current equipment found to be potentially sensitive to EMF. Other parts of Overlake Hospital are too distant to be affected, and Children's Hospital BCSC does not have any other equipment that would be of concern.

The Overlake portable MRI unit trailer is located over 100 feet from proposed East Link alternative routes. The Children's Hospital BCSC MRI unit is located approximately 95 feet from proposed turnaround track in the MF1. The Children's Hospital site is also located just north of an existing Puget Sound Energy overhead electric transmission line and electrical substation.

The EMF level for the East Link light rail train operating in Alternatives C3T, C4A, C7E, and C8E over I-405 is expected to be 0.6 milliGauss (mG) at a distance of 220 feet from the MRI unit at Overlake Hospital. (A milliGauss is a unit of intensity of a magnetic field.) The EMFs from the East Link Project routes would have a lower magnitude than those existing near the Overlake MRI Unit, as shown in Table 4.13-2; therefore, the fields from these sources should not cause a problem for the continued successful operation of this unit.

The Children's Hospital BCSC MRI unit is located inside a shielded room on the second floor. The shielding would be expected to lower the level of EMF penetrating from the outside. The MRI in the shielded room would be approximately 240 feet from the operation of Alternatives C3T, C4A, C7E, and C8E south of the hospital. These conditions may result in approximately 0.5 mG transient magnetic field at the shielded MRI room whenever trains pass at full speed (up to 55 miles per hour [mph]). The MRI would be approximately 95 feet from the south turn around loop track at the MF1. Trains operating on this track would be operating at slow train speed (approximately 8 mph speed in the maintenance facility) that would result in an exposure to the MRI shielded room of about 1 mG. Given the existing exposures from sources in or near the BCSC (see Table 4.13-1), especially from cars moving in the BCSC parking garage immediately below the MRI unit (approximately 20 mG), the EMF from East Link operations is not expected to have an impact on the facility.

Stray Currents

Without control measures, a portion of the electrical current flowing through the light rail trains could stray into a buried pipe or cable, then flow along conducting utility lines in the ground back to the traction power substation. To avoid this issue, however, Sound Transit would coordinate control measures with entities that own and operate the utility lines that could be affected.

Sound Transit would minimize or avoid the potential for stray current impacts by selecting best management practices (BMPs) appropriate for the circumstances. The BMPs may include one or a combination of the following:

- Installing cathodic protection systems in nearby utility lines to protect them from corrosion
- Installing insulating unions to break the electrical conductivity of the pipe and thus force the stray current to take another path
- Isolating the electrical rails from ground
- Installing stray-current-control track-fastening systems where appropriate:
  - Tie-and-ballasted track using high-resistance track-fastening systems on concrete ties
  - Direct-fixation track using high-resistance, rubberized track-fastening systems
  - Embedded track using various methods of rail encapsulation such as rail coatings, polyurethane encasement, and rail boots

New natural gas and water lines routed below East Link tracks, and/or new piping systems close to the tracks, would require cathodic protection systems. Cathodic protection system components include the following:

- Galvanic anodes
- Electrical isolation with insulating unions at connections to existing piping
- Pipe coatings
- Bonded mechanical pipe joints
- Permanent test facilities to monitor stray currents and rates of corrosion

Where tracks are elevated on overhead guideway structures, the return current cannot get to ground as easily as on structures that are not elevated; therefore, EMFs from overhead structures are less likely to affect underground utility lines.

Sound Transit and an Independent Review Team (IRT), a team of engineering experts funded by the Washington state legislature and overseen by the Joint Transportation Committee, have investigated the potential impacts of stray current on the Homer M. Hadley (I-90) floating bridge. The concern is that stray current could cause corrosion in the bridge structure, thereby reducing the lifespan of the bridge. To address this concern, the IRT has recommended three layers of protection: isolating the rail by constructing special insulating systems, installing a stray current collector mat, and potentially upgrading the cathodic protection system. An upgraded cathodic protection system could be attached to the floating bridge to mitigate stray current leakage from the light rail track that may accumulate in the reinforcing steel used on the floating bridge. The project would also place a monitoring system on the bridge to monitor stray current levels. Additionally, the cathodic protection system for the adjacent Lacey V. Murrow floating bridge may also be upgraded. With these measures in place, no impact on either bridge would be expected.

Potential Health Effects from Light Rail Alternatives

EMFs can cause a variety of impacts on humans. Certain EMF combinations can cause shock and burn injuries through direct contact with energized components; others can interfere with the operation of electrical and magnetic devices, including heart pacemakers. Based on data available from similar rail systems, however, operation of the light rail is unlikely to generate health impacts for riders or people along the tracks. Anticipated EMF intensities at locations of human exposure within and adjacent to the light rail line are considerably below exposure guidelines established by the American Conference of Governmental Industrial Hygienists and the more recent guidelines established by the International Commission on Non-Ionizing Radiation Protection. These guidelines address known biological effects and do not address speculative concerns about cancer and other possible health effects. Given uncertainties in potential biological effects, these guidelines do incorporate safety factors. Among the various alternatives, no notable differences exist in potential health impacts related to EMFs.

4.13.3.3 Impacts during Construction

No impacts from EMF on nearby sensitive facilities are anticipated during construction.

4.13.4 Potential Mitigation Measures

No mitigation measures for EMI from the East Link Project are needed for sensitive equipment at Overlake Hospital or Children’s Hospital BCSC because the projected EMF from East Link is lower than the existing EMF environment. Standard design measures are necessary for protection against stray currents. These measures would be developed and implemented in consultation with utility owners during final design.

The I-90 section of the light rail would incorporate measures to prevent stray electrical current from corroding the steel components of the I-90 bridge, as agreed to with WSDOT.

4.14 Public Services

4.14.1 Introduction to Resources and Regulatory Requirements

This section discusses public services located within the study area or with service boundaries within the study area. The study area is defined as a 0.5-mile boundary around the project alternatives. The public services that were considered are fire and emergency medical services (including hospitals), police, schools (public and private), mail delivery services, and solid waste and recycling collection in the cities of Seattle, Mercer Island, Bellevue, and Redmond. This section also reviews project-related operations that might lead to increases or changes in emergency response services related to crime or other emergency response incidents.

A safety and security management plan (SSMP) is required for major capital projects funded through the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) as indicated in the Federal Transportation Administration (FTA) Circular C5800.1 (FTA, 2007). The SSMP is used to establish the safety and security organization required for the project as well as to integrate safety and security throughout the project life cycle (i.e., design, construction, and operation). Required SSMP contents relevant to fire and emergency medical services include creating a Fire/Life Safety Committee; developing safety, security, and emergency plans; and implementing emergency preparedness (i.e., exercises and drills) to provide a safe environment for Sound Transit passengers, employees, and persons interacting with the project.

4.14.2 Affected Environment

This section discusses the location and service areas for fire, police, emergency providers, hospitals, schools, and solid waste and recycling collection located within the study area. Exhibits showing these facilities are located in Section 4.4, Social Impacts, Community Facilities, and Neighborhoods (see Exhibits 4.4-1 through 4.4-6). The following subsections describe the affected environment for key public services.

4.14.2.1 Fire and Emergency Medical Services

The Cities of Seattle, Mercer Island, Bellevue, and Redmond provide fire and emergency medical services within the study area. The outcome of emergency situations can be determined within minutes of the response. Any delay can make a difference in the effectiveness of the response to an accident or other incident. The following key medical emergency facilities within or near the study area serve the study area:

- Harborview Medical Center, located at 325 9th Street in Seattle, is the nearest hospital to Segment A (see Exhibit 4.4-1 in Section 4.4, Social Impacts, Community Facilities, and Neighborhoods). The Harborview Medical Center is also the headquarters for the Seattle Fire Department’s Medic One Program that provides advanced life-support activities and responds to fires, hazardous materials calls, and rescue calls within the Segment A study area.
- Overlake Hospital Medical Center, a regional medical center, is located at 1035 116th Avenue NE in Bellevue (see Exhibit 4.4-5). Overlake Hospital Medical Center is also the location of one of the four Medic One units that provide service to eastern King County, including Bellevue.
- Group Health Cooperative has two facilities in the study area. The Bellevue Medical Center, located at 11511 NE 10th Street, is immediately south of Overlake Hospital Medical Center, and the Redmond Medical Center at Riverpark, at 15809 Bear Creek Parkway, is located in Downtown Redmond.

In addition, the Bellevue Public Safety Training Center, located at 1838 116th Avenue NE (see Exhibit 4.4-5) in Segment D provides training facilities and services for City of Bellevue police and fire personnel, regional emergency services, the King County Sheriff’s Office, and other rescue groups. This facility also includes a helicopter landing facility.

Seattle, Mercer Island, and Bellevue have prepared response plans and made mutual aid agreements related to responding to calls along Interstate 90 (I-90). They employ a seamless response, which means the closest unit to an incident is dispatched and is not focused on the jurisdiction. The Seattle Fire Department responds to calls eastbound across the I-90 floating bridge. The Department also takes advantage of the D2 Roadway (the high-occupancy vehicle [HOV] ramps) from Seattle to I-90. The Mercer Island Fire Department is responsible for incidents along the I-90 corridor in the westbound direction from the East Channel bridge to west of the Mt. Baker Tunnel and eastbound from the I-90 floating bridge to the Factoria exit. If the peak direction traffic flow permits, then these departments use the I-90 center roadway to access the emergency scene should the westbound or eastbound lanes be congested or hamper the ability to travel to the scene of the incident

(Tubbs, 2007). The Mercer Island Fire Department does not use the 60th Avenue ramp access to the center lanes because it cannot accommodate the turning radius needed for fire trucks and because of its insufficient sight distance.

Table 4.14-1 lists the average response times (i.e., the elapsed time, in minutes) from when the first company of a responding department is dispatched to when the first company arrives at the emergency scene.

4.14.2.2 Police

The police departments for the cities of Seattle, Mercer Island, Bellevue, and Redmond patrol and respond to calls within the city limits for each city within the study area. Average response times for the police departments are approximately 6.5 minutes for Seattle, less than 6 minutes for Mercer Island, and approximately 6 minutes for Bellevue. The City of Redmond does not typically release its average response times. In addition to the police departments within each jurisdiction, the Washington State Patrol also responds to calls for service along I-5, I-90, I-405, State Route (SR) 520, and SR 202, and the King County Sheriff's Office responds to calls along King County Metro routes. Both of these agencies also assist other agencies through mutual aid agreements. Sound Transit contracts with the King County Sheriff's Office and works in partnership with local law enforcement to create a safe regional transit system. The Washington State Patrol and the King County Sheriff's office do not record and maintain response time statistics.

The King County District Court, East Division, Bellevue Facility, at 585 112th Avenue SE (see Section 4.4, Exhibit 4.4-4), provides court services for the cities of Bellevue and Newcastle and is located within Surrey Downs Park in Segment C. King County plans to relocate the facility.

Sound Transit compared Uniform Crime Reporting Program data for the study area with King County and Washington State numbers to illustrate the crime rates at a local, regional, and statewide scale. The review covered the years 2006, 2007, and 2008. The program was created to provide uniform crime statistics for the nation and maintains criminal statistics for violent crimes (i.e., murder, forcible rape, robbery, and aggravated assaults) and property crimes (i.e., burglary, larceny-theft, motor vehicle theft, and arson).

Overall, the total number of crimes has gradually decreased over the past 3 years in the study area for Seattle, Redmond, and King County, as well as for Washington State. Crime statistics for Mercer Island and Bellevue show a small drop in 2007 and a small increase in 2008. Table 4.14-2 compares violent and property crimes in the study area cities with crimes at the county and state level.

4.14.2.3 Schools

The East Link Project alternatives are located within the following school districts: Seattle School District, Mercer Island School District, Bellevue School District, and Lake Washington School District. In addition to the public schools, private schools and a postsecondary school are also located within the study area. Schools within the study area are illustrated in Section 4.4, Exhibits 4.4-1 to 4.4-6. Elementary school students in all of the school districts use school bus transportation provided by the districts. In addition to the bus transportation provided by the school districts, middle school and high school students also use King County Metro buses. Students who attend Lake Washington Technical College primarily use their own vehicles.

4.14.2.4 Solid Waste and Recycling Collection

The following companies provide solid waste and recycling collection for the jurisdictions within the study area:

TABLE 4.14-1
Fire Department Average Response Times

Responder	Average Response Time		
	Fire, Rescue, Hazard Materials	**Basic Life Support**	**Advanced Life Support**
Seattle Fire Department (2008 data)	4.32 minutes	3.75 minutes	3.76 minutes
Mercer Island Fire Department (2006 data)	8.50 minutes	6.17 minutes	6.17 minutes
Bellevue Fire Department (2005 data)	6.57 minutes	6.57 minutes	6.57 minutes
Redmond Fire Department	Not Available	Not Available	Not Available

Source: Seattle Fire Department, 2008; City of Mercer Island, 2007; City of Bellevue, 2007

TABLE 4.14-2
2008 Violent and Property Crime Rates

Jurisdiction	Part I Offenses (Violent and Property Crimes)	Violent Crime Rate (per 1,000 population)	Property Crime Rate (per 1,000 population)
Seattle	36,346	5.8	55.5
Mercer Island	436	0.6	18.7
Bellevue	4,478	1.4	36.2
Redmond	1,751	1.3	32.9
King County	7,693	1.6	20.9
Washington State	264,158	3.2	36.9

Source: Washington Association of Sheriffs and Police Chiefs, 2008.

- Waste Management and Cleanscapes are currently contracted to provide commercial and residential collection within the Seattle portion of the study area. Waste Management provides services south of I-90 and Cleanscapes provides services north of I-90. Solid waste collected in Seattle is currently shipped to landfills outside of King County.
- Rabanco Eastside Disposal and Recycling provides residential and commercial collection within Mercer Island and Bellevue. Materials are taken to two transfer facilities located outside of the study area (Houghton Transfer Station in Kirkland and the Factoria Transfer Station in Bellevue). Solid waste collected at these facilities is compacted and taken to the Cedar Hills Regional Landfill in Maple Valley.
- Waste Management is contracted to provide solid waste collection and recycling from residential and commercial customers for the City of Redmond.

Collection vehicles travel throughout the roadways in the study area.

4.14.2.5 Other Public Services

There are several U.S. Postal Service facilities in the study area vicinity, as follows:

- Pioneer Square, 91 South Jackson Street, Seattle
- International, 414 6th Avenue South, Seattle
- Terminal Finance Station, 2420 4th Avenue South, Seattle
- Mercer Island, 3040 78th Avenue SE, Mercer Island
- Bellevue, 1171 Bellevue Way NE, Bellevue
- Midlakes, 11405 NE 2nd Place, Bellevue
- Crossroads, 15731 NE 8th Street, Bellevue
- Redmond, 16135 NE 85th Street, Redmond
- Redmond Carrier Annex, 7241 185th Avenue NE, Redmond

There is a U.S. Social Security Administration facility at 505 106th Avenue NE in Downtown Bellevue and at 675 South Lane Street in the International District in Seattle.

4.14.3 Environmental Impacts

Public services might be affected by project operation or by project construction. Sound Transit determined impacts by reviewing design drawings and documentation related to project construction to identify what could cause changes in the travel and response times for public service vehicles or impede access to public service facilities. Documents reviewed included those prepared for similar light rail projects: the Seattle Strategic Planning Office document *Staying on Track: Review of Public Safety and Security on Light Rail Systems* (City of Seattle, 1999) and *The Geography of Transit Crime: Documentation and Evaluation of Crime Incidence on and around the Green Line Stations in Los Angeles* (Loukaitou-Sideris et al., 2002). Sound Transit qualitatively compared the crime rates of the cities within the study area with the overall crime rate of King County and then performed literature reviews associated with crime and light rail systems to evaluate potential crime level increases from the project.

This section summarizes the impacts that could result from the East Link Project and the No Build Alternative. For the project, the discussion of impacts covers the general impacts that are common to all segments, and then the key impacts for each segment are discussed.

4.14.3.1 No Build Alternative

The No Build Alternative would have no impacts on public service in the study area.

4.14.3.2 Impacts during Operation

Impacts Common to All Alternatives

Safety is one of the Sound Transit design criteria used to avoid conflicts with vehicular, bicyclist, and pedestrian traffic. The East Link alternatives are located within exclusive or semiexclusive (for at-grade profiles) rights-of-way. Implementing the required SSMP would minimize impacts on fire and emergency medical services during project operation. The project would not lead to an unplanned or induced increase in population, so it would not require additional public services beyond those already planned.

Fire and Emergency Medical Services

The project would be predominantly in its own (exclusive) right-of-way and it would have minimal conflicts with vehicular traffic, bicycles, and pedestrians. In addition, emergency incidents on the project are expected to be minimal because the facilities would be made of nonflammable materials. The vehicles would be electrically powered and would not use combustible fuels.

Fire and emergency service vehicles would have to use different methods and, in some cases, different equipment, when responding to incidents associated with at-grade, elevated, and tunnel profiles. The following text provides information on the methods that would be used to respond to incidents associated with these different profiles.

The at-grade alternatives would not share the right-of-way travel lane with other vehicles because the at-grade right-of-way would be semiexclusive and curb separated from vehicles, except at intersections with cross traffic. Intersection crossings would be designed to provide light rail vehicles with priority signaling over automobile movements. In addition, it is expected that vehicle traffic would have separated left-hand turn lanes with their own signal time; however, emergency response vehicles would be allowed to make these turns at their discretion. To prevent conflicts at unsignalized at-grade crossings, there would be gates with bells to warn people. The vehicles would also have bells and horns. Bells, gates, and horns are activated according to safety guidelines.

Raised curbing is expected to minimize accidents between light rail vehicles and general traffic. However, in certain sections to be determined during final design, the raised curbing would be mountable, allowing emergency response vehicles to travel across the light rail tracks. In areas where there is no mountable curbing, emergency response vehicles would need to take longer routes by backtracking from the next signalized intersection or taking other routes through to the incident. In general, light rail vehicles that travel without gates have a lower signal priority than EMS and law enforcement vehicles in order to improve response times and increase safety of first responders. Light rail trains that cross streets/intersections with automatic gate crossings require emergency vehicles to yield for their movement. However, there are exceptions depending on the prevailing situation. As part of Sound Transit's work with local jurisdictions, further details associated with signal prioritization and protocols would be developed.

Fire department regulations and procedures prevent placing fire hoses over active railroad tracks, so light rail operations would need to temporarily shut down during emergencies. Design considerations could include placing additional fire hydrants on either side of at-grade tracks to avoid laying fire hoses over the tracks. In the event of an emergency incident, access for fire and emergency medical services to elevated and tunnel sections of the track and stations would be more difficult than on the at-grade sections. Access to trains on elevated and tunnel sections would likely be provided via trains on the adjacent guideway. Emergency service providers and Sound Transit personnel would be trained to respond to emergencies.

Access to tunnel sections would be maintained for prompt response times and for the safety of passengers and emergency service providers. To minimize impacts during operation, tunnels and elevated sections would be designed to provide emergency access and evacuation in conformance with state and local codes and with *NFPA 130: Standard for Fixed Guideway Transit Systems, 2010 Edition* (National Fire Protection Association [NFPA], 2010). Methods of access and evacuation that could be implemented during emergencies on the elevated and tunnel sections of rails and stations include using another train on the adjacent track, stairways (public and emergency), emergency walkways, escalators, and elevators as applicable and as long as it is safe to do so. Responders would use water standpipes or other fire fighting and emergency features incorporated in the light rail design. When a second train is not practical, Sound Transit would follow state and local fire codes and NFPA 130. All local fire departments in the study area have ladder trucks to properly respond to elevated incidents.

The tunnel stations would include a number of safety design features. Design features to address fire prevention, ventilation and fire protection, and evacuation could include the following:

- Tunnels and underground stations would be constructed of noncombustible materials.
- Automatic fire suppression equipment would protect electrical components.
- Systems of emergency ventilation shafts, fans, and dampers would direct fresh air into selected areas and remove smoke from areas during an emergency.
- Passengers would be evacuated by reversing trains out of the tunnel; transferring passengers to a rescue train; allowing passengers to exit the tunnel by using elevators or emergency stairways or by walking out of the tunnel; or by having passengers use a cross passage (a passage connecting the two tunnels) to access the other tunnel.
- Signs would be located in tunnels to identify the locations of passages and station and tunnel openings.
- Tunnels would include emergency lighting, telephone connections, and underground communications for safety officials.

A required component of the SSMP is the formation of the Fire/Life Safety Committee, which is reviewing safety requirements and obtaining concurrence from local authorities that have jurisdiction. The Fire/Life Safety Committee comprises representatives from local fire, police, and building code agencies and from Sound Transit. The Fire/Life Safety Committee would develop solutions regarding access to the light rail system, emergency routes, water and fire hydrant needs, training, costs, and other design features so that the light rail system would not compromise fire and life safety in the project vicinity. In addition, safety and security issues would be reviewed at community meetings to identify and address concerns and potential hazards and vulnerabilities.

In addition to the Fire/Life Safety Committee, Sound Transit would continue to consult local jurisdictions throughout design to minimize impacts from the project on response time and accidents requiring fire and emergency medical vehicles. In addition, precise emergency procedures and necessary equipment would be determined during final design. Sound Transit also has a Safety Outreach Program that reaches out to the community to encourage safe driving, bicycling, and walking behavior around the light rail alignment to prevent accidents.

Police

Police vehicles traveling along the light rail corridor should not experience increased response times in areas of exclusive right-of-way. In areas where there is semiexclusive right-of-way, police vehicles would have the same issues described above for fire and emergency medical services. In addition, similar to fire and emergency medical responders, police could experience difficulty in responding to calls at elevated or tunnel sections of track or stations. However, generally, trains would proceed to the nearest station for a response.

A literature review found that crime occurring at stations is directly related to crime levels in the surrounding area. The most common types of crimes relate to property crime and quality of life crimes (i.e., vandalism, public drunkenness, and littering), with violent crime comprising only a small percentage. If crimes were to occur along the project corridor, then it would likely occur at a station or a park-and-ride lot. However, increases in activity (i.e., number of people) and the introduction of security measures could act as a deterrent to crime.

Sound Transit contracts with the King County Sheriff's Office and works in partnership with local law enforcement to create a safe regional transit system. 2010 crime statistics show that the crime rate per number of riders at transit facilities and on light rail and commuter rail trains is substantially lower compared with overall per capita crime rates in Seattle, Tukwila, and SeaTac.

Sound Transit applies principles of Crime Prevention through Environmental Design (CPTED), uses specific hardware and equipment, and employs personnel at the stations as well as on the trains to reduce the potential for criminal activities. The stations would be designed using CPTED principles and include numerous features to address security issues. The design of the stations would be spacious, well lit, and uncluttered and would provide open access. Attention would be given to lines of sight and visibility, with corners, dark or hidden areas, and opaque shelter screens eliminated or minimized. Public waiting areas, including station platforms, would be easily visible to other patrons and to police and Sound Transit security personnel. CPTED design measures minimize impacts by controlling passenger movements with specified traffic flow patterns or a central platform; creating areas that can be easily viewed by closed-circuit television (CCTV) cameras or persons (including transparent exterior walls and good lighting); using vandalproof surfaces and lighting; and using easily maintained materials.

Other measures to minimize crime include using equipment (i.e., CCTV, sealed fareboxes on ticket vending machines, and automatically sealed exits), using anticrime programs (such as anti-graffiti programs), and having Sound Transit police, police from local jurisdictions, and Sound Transit security personnel patrol the stations and the trains. In areas where Sound Transit would provide public restrooms at terminus stations, the restrooms would be located in a safe and secure area of the facility; would provide CCTV security in entry areas and the restrooms; would use durable, easily cleanable, and vandal-resistant materials for construction, including lighting; and would locate the restrooms where they would not conflict with the facility operations or general traffic flow. Sound Transit would implement these measures as appropriate.

Uniformed police officers and Sound Transit security personnel would police the East Link Project during operation (i.e., 20 hours a day). Light rail train operators would be trained in how to respond in emergencies. There would be CCTV cameras feeding images to a 24-hour security office and a passenger emergency telephone at each station platform that connects patrons directly to the security office. Public address systems and variable message signs would be provided in stations throughout the system, as would public telephones at stations.

Sound Transit would build upon existing plans (i.e., *University Link Safety and Security Management Plan, SSMP 2010* [Sound Transit, 2010]) and use its existing design criteria (i.e., design requirements for lighting, unobstructed views, vandalism, alarms, and other measures) to meet the latest FTA guidelines on safety and security. In addition, as part of the SSMP, Sound Transit would address how the project would meet U.S. Department of Homeland Security requirements, including applicable security directives issued by the Transportation Security Administration, in order to address issues related to terrorist threats.

Consistent with literature findings that crime is reflective of the surrounding neighborhoods, no adverse impacts on police services are expected.

Schools

No project alternative would acquire any school property, nor would any alternative travel within established grade school-crossing zones. For the most part, East Link Project alternatives would not travel through residential neighborhoods where school buses travel to pick up elementary school children. The *Transit Service Integration Plan* (Sound Transit, 2007a), developed in cooperation with King County Metro, shows that Metro bus routes would either be modified or eliminated to complement the East Link Project; therefore, no adverse impacts related to school transportation are anticipated. Chapter 3, Transportation Environment and Consequences, explains that there would be overall improved transit travel times. Some school bus routes might need to be modified where left turns conflict with at-grade alternatives.

Postal Services

No adverse impacts on postal collection or delivery in the East Link study area would occur during light rail operation. No postal routes would be negatively affected or experience delay or altered services due to changes in existing roadways. Some collection routes might need to be rerouted where left turns conflict with at-grade alternatives.

Solid Waste and Recycling Collection

No adverse impacts on solid waste collection and disposal in the East Link study area would occur during light rail operation. No collection routes would be negatively affected or experience delay or altered services due to changes in existing roadways. Some collection routes might need to be rerouted where left turns conflict with at-grade alternatives.

Segment A

Fire and Emergency Medical Services

For *Preferred Interstate 90 Alternative (A1)*, Sound Transit has completed a *Mount Baker and First Hill Tunnel/Lids Draft Fire and Life Safety Report* (Sound Transit, 2007b), which identifies the existing conditions and applicable code requirements and recommends retrofitting the existing tunnels in order to provide a safe environment for Sound Transit passengers, employees, and emergency response providers. The report also recommends training for transit and emergency service providers at least twice each year during operation. There are two design options for the light rail tracks with *Preferred Alternative A1*: (1) direct fixation rails with the tracks located on top of the road surface, and (2) embedded rails where the tracks are embedded into the road surface. With direct rail fixation, standard light rail tunnel emergency response procedures would have to be implemented, including accessing emergencies with another light rail car or rail vehicle. With the embedded rails, fire and emergency medical vehicles would be able to drive their equipment into the light rail tunnel when responding to any calls within the tunnel(s) or adjacent tunnels.

Converting the I-90 center roadway for use by light rail vehicles for *Preferred Alternative A1* would prevent large emergency vehicles (i.e., fire trucks and ambulances) from using the center roadway.

Currently, emergency vehicles can use the center roadway when traffic in this HOV lane is going in the direction that they are traveling. Limited emergency access to the center roadway would still be available via the maintenance roadway, but in general, emergency response would be restricted to the outer roadways of I-90, most likely the HOV lanes. Without the unrestricted ability to use the center roadway, response times for emergency vehicles could increase depending on the congestion levels on I-90. However, as discussed in Chapter 3, Transportation Environment and Consequences, congestion periods would be fewer with the project than without.

The *Preferred Alternative A1* design option for joint use of the D2 Roadway (part of the I-90 center roadway) with buses might allow the Seattle Fire Department to continue to use the D2 Roadway (HOV lanes) when responding to calls. In addition, a safety and security plan for D2 Roadway joint operations would be developed and implemented before joint bus and rail use begins. If the D2 Roadway becomes rail only, then fire and emergency vehicles would need to use the other I-90 ramps and the local arterial street network to access incidents; as a result, response times might be impacted.

Police

The Rainier Station with *Preferred Alternative A1* is surrounded by a neighborhood with a crime rate that is the highest in the study area and higher than the county average. This station would be designed with camera surveillance, bright lighting, and other security measures. Sound Transit security personnel would monitor this station as necessary. Similar to fire and emergency vehicles, police vehicles would also lose access to the I-90 center roadway, which would result in impacts similar to those discussed under Segment A, Fire and Emergency Medical Services.

Segment B

Fire and Emergency Medical Services

For both *Preferred 112th SE Modified Alternative (B2M)* connecting to *Preferred Alternative C11A* or *C9T,* there would be minimal access issues for emergency service providers because the alternatives would be located east of Bellevue Way SE and 112th Avenue SE, and there are few access points. *Preferred Alternative B2M* connecting to *Preferred Alternative C9T* includes a design option to close access into Bellefield Office Park at SE 15th Street; however, a crash gate would remain in order to maintain current emergency access service. *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* would cross over to the median of 112th Avenue SE and would require a gate for northbound traffic. Should a light rail train be crossing over the northbound lanes during a response to an emergency, there could be a slight increase in response time. Sound Transit would install EMS signal-priority devices to minimize this occurrence.

Of the other Segment B alternatives, only Alternative B1 might affect emergency service. Alternative B1 would travel directly in front of Bellevue Fire Department Station 1 but would not result in impacts on access and egress because there would be a signal with left-turn access allowed into and out of the fire station. Should a light rail train be passing in front of the station during a response to an emergency, there could be an increase in response time of a few seconds. Sound Transit would install EMS signal priority to minimize this occurrence. In addition, Alternative B1 north of the Bellevue Way SE and 112th Avenue SE intersection has more driveways to adjacent businesses and residences than the other at-grade Segment B alternatives, resulting in a greater access issue for emergency service vehicles.

Alternative B7 would result in the fewest access issues because most of the alternative is located within existing former BNSF Railway right-of-way. The 112th SE Elevated Alternative (B2E) would also result in minimal access issues because the alternative is elevated above the roadway and would not prevent access. The 112th SE At-Grade Alternative (B2A), 112th SE Bypass Alternative (B3), and the B3 - 114th Extension Design Option would have similar access issues along 112th Avenue SE, but there are not as many access points as there are along the Alternative B1 route, and therefore, there would be fewer and less severe impacts.

Police

Both *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* or *C9T* include a South Bellevue Station, which would have a structured park-and-ride facility. By implementing security measures at this structured park-and-ride facility (i.e., lighting and surveillance), the overall crime rate for the surrounding area is not expected to increase as a result of the presence of this facility. In addition, there is an existing park-and-ride lot (i.e., the Wilburton Park-and-Ride) located relatively close to the SE 8th Station, which is part of *Preferred Alternative B2M* connecting to *C9T*. Introducing light rail is unlikely to change the incidence of crime at the Wilburton Park-and-Ride. This station would not be built if the C9T - East Main Station Design Option was chosen. Police response times would have the same impacts as discussed in Fire and Emergency Medical Services in Segment B. Therefore, no impacts are anticipated on local police services.

Each of the other Segment B alternatives, except Alternative B7, would include a South Bellevue Station and an associated structured park-and-ride facility. Alternative B7 would include a station, the 118th Station, which would also have a structured park–and-ride facility. Similar to the structured park-and-ride facility at the South Bellevue Station under *Preferred Alternative B2M*, the 118th Station park-and-ride facility is not expected to increase crime in the surrounding area. Police response times would receive the same effects as discussed in Fire and Emergency Medical Services in Segment B. Therefore, no impacts are anticipated on local police services.

Segment C

Fire and Emergency Medical Services

Preferred Alternative C11A would remove access to 112th Avenue SE from SE 4th Street and also remove access to Main Street from 110th Avenue SE and 110th Place SE. Emergency vehicles would still be able to access homes in the Surrey Downs neighborhood from SE 1st Place, SE 2nd Street, and SE 11th Street. This change is expected to have a minor effect on emergency response times.

Preferred Alternative C11A would also result in a semiexclusive right-of-way in Segment C, which might affect emergency response on 108th Avenue NE. Vehicular traffic would be reduced to one lane in either direction on 108th Avenue NE, thereby reducing travel flow and slightly increasing response times for emergency vehicles using this road. *Preferred Alternative C11A* would also restrict left-hand turns at intersections and would cause minor increases in emergency response times. There would be no impacts on access to or from Overlake Hospital nor impacts to Group Health Medical Center from the I-405 crossing at NE 6th Street. Refer to Chapter 3, Transportation Environment and Consequences, for complete information on changes to intersection movements.

Preferred Alternative C9T would be predominantly grade-separated and is not expected to affect emergency response times due to the relatively minor changes it would make to the existing street network. This alternative is also not expected to affect access to or from Overlake Hospital Medical Center or Group Health Medical Center. This alternative would remove a portion of the King County District Court building; however, the County has plans to move this facility in the near future, and if that occurs, no operational impacts are anticipated.

Alternatives C4A and C9A would result in semiexclusive right-of-way in Segment C, which might affect emergency response on 108th and 110th Avenues NE. Traffic would be reduced in some sections of these roadways to one lane in either direction, thereby reducing travel flow and slightly increasing response times for emergency vehicles using these roadways. Both alternatives would also restrict left-hand turns at several intersections and would cause minor increases in emergency response times.

Alternatives C7E, C8E, and C14E would be predominately grade-separated (i.e., elevated) and are not expected to affect emergency response times in the area. Alternatives C1T and C2T would change NE 6th Street, east of the Bellevue Transit Center, from two lanes in each direction to one lane in each direction for one block in front of the Meydenbauer Center. Emergency response would not be affected by this change due to the relative short distance of roadway that would be affected. In addition, there would be no impacts on access to or from Overlake Hospital Medical Center for Segment C alternatives traveling on NE 12th Street, nor impacts to Group Health Medical Center from the I-405 crossing at NE 6th Street.

There would be no additional impacts or differences in impacts for the connectors from the Segment B and D alternatives associated with Segment C. The connectors from Segment B are either elevated or transition into a tunnel, and the connectors to Segment D are either within the former BNSF Railway right-of-way or elevated along NE 12th Street.

Police

Changes in police response times for *Preferred Alternative C11A* would be similar to those described under Fire and Emergency Medical Services for this alternative. *Preferred Alternative C9T* would include an underground station, the Bellevue Transit Center Station. Studies have shown that underground stations result in more crime than elevated or at-grade stations (Loukaitou-Sideris et al., 2002). However, because of Sound Transit design criteria for lighting, surveillance, and open corridors, and because of project-dedicated police monitoring, crime would be minimized. The impact on local police services as a result of this alternative is, therefore, expected to be minimal.

Other potential design features to address safety and security in tunnels could include the following:

- Spacious, well-lit, and uncluttered station areas with uniform lighting throughout
- Central control center with CCTV monitoring the station, elevators, and stairwells

- Sound Transit staff in a central control center able to operate elevators, fire doors, air vents, and electricity as well as monitor train operations
- Light rail train operators with the capability to provide additional watch in the tunnel and report any problems to the central control center
- Passenger assistance telephones to provide direct contact with security or emergency response personnel
- Roving security personnel

Under *Preferred Alternative C9T*, the north entrance to the Bellevue Transit Center Station would be located adjacent to Bellevue City Hall, which houses the Bellevue Police Department. This alternative would also remove parking at the Bellevue City Hall parking garage. This parking impact is not expected to have a negative effect on local police services. The potential at-grade C9T - East Main Station Design Option would be unlikely to change the incidence of crime along 112th Avenue SE. Because police response times would not be affected, no impacts are anticipated on local police services.

The underground stations associated with Alternatives C1T, C2T, and C3T would have minimal impacts on local police services for the same reasons as those described under Police for *Preferred Alternative C9T*. Alternative C9A would result in the loss of parking at Bellevue City Hall, but to a lesser degree than that described under *Preferred Alternative C9T*. The Bellevue Police Department is also housed at Bellevue City Hall, but this parking loss is not expected to result in a negative impact on local police services. In general, police response times would have the same effects as discussed under Fire and Emergency Medical Services in Segment C. In addition, Alternatives C2T and C3T connecting from Alternative B2A would relocate the King County District Court; however, the County has plans to move this facility in the near future, and if that occurs, then no operational impacts are anticipated.

Segment D

Fire and Emergency Medical Services

Preferred NE 16th At-Grade Alternative (D2A) would cross the intersection of NE 16th Street and 132nd Avenue NE at-grade just south of Bellevue Fire Department Station 6. Should a light rail train be in this intersection during a response to an emergency, there could be a slight increase of a few seconds in response time. Sound Transit would install EMS signal priority to minimize this effect.

Under the NE 20th Alternative (D3), the retained-cut sections along NE 20th Street and 152nd Avenue NE would restrict left-turning movements except at intersections, causing emergency service vehicles to backtrack for some incidents. This would not substantially affect response times, because major intersections would be preserved. Alternative D3 would also cross the intersection of NE 16th Street and 132nd Avenue NE at-grade just south of Bellevue Fire Department Station 6, similar to *Preferred Alternative D2A*. Alternative D3 would have a similar effect on response times from this station as *Preferred Alternative D2A*, and similarly, Sound Transit would install EMS signal priority to minimize this effect.

Police

Preferred Alternative D2A would include structured park-and-ride lots in Bellevue and Redmond (130th and Overlake Transit Center Stations, respectively). These facilities would include the same security design measures as listed for Segment B, resulting in no substantial impact on police services.

Police vehicles would be subject to the same access issues as those described in Fire and Emergency Medical Services for Alternative D3. Alternatives D2E, D3, and D5 would include structured park-and-ride lots in Bellevue and/or Redmond (130th and Overlake Transit Center Stations, respectively) depending on the alternative. These facilities would include the same security design measures as listed for Segment B, resulting in no substantial impact on police services.

Segment E

Fire and Emergency Medical Services

With *Preferred Marymoor Alternative (E2)*, no additional impacts on fire or medical response services are anticipated other than those discussed under Impacts Common to All Alternatives. No additional impacts on fire or medical response services are anticipated other than those discussed under Impacts Common to All Alternatives. The E2 - Redmond Transit Center Station Design Option would travel along 161st Avenue NE adjacent to Redmond Fire Department Station 11 but would not affect response times for emergency services because emergency vehicles exit the station onto NE 85th Street.

Police

No additional impacts on police response times with *Preferred Alternative E2* are anticipated other than those discussed under Impacts Common to All Alternatives. *Preferred Alternative E2* would include a structured park-and-ride lot at the SE Redmond Station that would include the same security design measures as listed for Segment B, resulting in no substantial impact on police services.

With the other Segment E alternatives, no additional impacts on police response times are anticipated other than those discussed under Impacts Common to All Alternatives. Alternatives E1 and E4 both would include a structured park-and-ride lot at the SE Redmond Station with the same security design measures as listed for Segment B, resulting in no substantial impact on police services.

4.14.3.3 Impacts during Construction

Impacts Common to All Alternatives

Construction of the project alternatives would result in increased congestion along adjacent roadways as a result of temporary lane and roadway closures, shifts in roadway alignments, detours necessary for construction, and construction activities associated with the project. This could affect access and response times for public service providers (i.e., fire and emergency medical, police, school buses including King County Metro buses, and solid waste and recycling vehicles). However, Sound Transit would make provisions to maintain the required access during established periods or keep one lane of traffic open (especially on main arterials) and, whenever possible, accommodate additional access during peak travel hours. Prior to construction, traffic control plans would be reviewed and approved by applicable agencies before implementation.

Prior to construction, Sound Transit would coordinate with public service providers on required detour routes and lane closures in order to minimize increases in travel and response times and to avoid interference with the collection of solid waste and recyclables or the transportation of students. As a result, public services would not be adversely affected during construction.

Fire and Emergency Medical

During construction, access and egress for fire and emergency medical vehicles would be maintained at all times, which would minimize impacts on response and travel times within all project segments. Emergency service providers might need to develop contingency plans in coordination with Sound Transit to reduce response and travel times. Coordination would need to occur with any fire departments where construction might affect access to hydrants or require water line relocations. In addition, during construction, the Fire/Life Safety Committee would address any safety issues that happen to arise and propose changes that could affect safety.

Police

In high-traffic and/or pedestrian locations, additional police might be required to direct tunnel traffic, especially in areas where trenching for tunnel, retained-cut, and elevated sections would occur, to minimize impacts on vehicles and pedestrians. Sound Transit would coordinate with the different jurisdictions and the Washington State Patrol to provide adequate police staffing. Police might need to respond to additional incidents associated with traffic congestion due to construction activities, especially along primary arterials. Construction might involve closing roadways for periods of time. Circulation changes would be coordinated with the local police and emergency service providers ahead of time.

Schools

There would be no construction close to schools; therefore, there would be no impacts associated with construction, such as noise and dust, on students or school employees. Construction could result in the temporary rerouting of school buses, along with King County Metro and Sound Transit buses, that might affect middle and high school students. In addition, construction could require temporarily relocating transit bus stops; however, this is not anticipated to affect middle and high school students because it is expected that bus stops would be relocated in the near vicinity.

Postal Services

Postal vehicles could experience delays; however, access and egress for postal vehicles would be maintained at all times to minimize impacts. If certain access points need to be closed, then alternative access points would be developed in coordination with the local post office.

Solid Waste and Recycling Collection

Collection vehicles could experience delays on collection routes; however, access and egress for solid waste and recycling collection vehicles would be maintained at all times to minimize impacts on collection. If certain access points are required to be closed, alternative access points, collection locations, or other measures would be developed in coordination with the solid waste and recycling companies. Construction activities would increase the amount of construction and demolition debris; however, there are a number of facilities in the Puget Sound region where the materials could be disposed or recycled, so no impacts are anticipated.

Segment A

On I-90, construction for *Preferred Alternative A1* would primarily occur within the existing center roadway, separate from westbound and eastbound traffic; therefore, impacts on public services would be minimized. The center roadway would not be available for access to incidents on the outer roadways. This could result in impacts on response times. The new I-90 two-way HOV lanes would be operating during construction of the East Link Project and would provide emergency vehicles with another travel lane to bypass general traffic. Emergency vehicles might need to respond to incidents within the I-90 center roadway during construction and might need to use the outer roadways to access such an incident.

Segment B

Preferred Alternative B2M connecting to *Preferred Alternative C11A* or *C9T* would not result in any additional construction-related impacts other than those described above under Impacts Common to All Alternatives. However, *Preferred Alternative B2M* connecting to *Preferred Alternative C11A* would have a generally higher level of disruption and access issues because it would shift from the east side of 112th Avenue SE to the center of 112th Avenue SE and continues north in the center of this road until reaching Segment C, as opposed to remaining on the east side of 112th Avenue SE with *Preferred Alternative B2M* connecting to *Preferred Alternative C9T*.

There are no additional impacts other than those described above under Impacts Common to All Alternatives; however, there are differences between the alternatives in terms of disruption and access. Alternative B1 would cause more disruption to circulation and public service access because of the greater number of access points to businesses and residences compared with the other Segment B alternatives. In addition, Alternative B1 would require construction to occur directly in front of Bellevue Fire Department Station 1, which might require additional measures to make sure access and egress is maintained. Alternative B7 would have the least impact on circulation and public access because construction would occur within former BNSF Railway and Washington State Department of Transportation (WSDOT) rights-of-way where there are no access or egress points. Access to these rights-of-way would be provided to emergency service providers to respond to emergencies.

Segment C

Construction of *Preferred Alternative C11A* or *C9T* would not result in any additional construction-related impacts other than those described above under Impacts Common to All Alternatives. Construction of the cut-and-cover tunnel under *Preferred Alternative C9T* would likely result in a longer and more intense period of construction than *Preferred Alternative C11A* and would likely result in more general disruption and public service access issues along 110th Avenue NE, including temporary restrictions on ingress and egress from the parking area at Bellevue City Hall, which houses the Bellevue Police Department. In addition, under *Preferred Alternative C9T*, the Bellevue Fire and Police Departments would require special training for any incidents that could occur associated with tunnel construction. This training would be developed as part of the SSMP and in coordination with the Fire/Life Safety Committee.

Construction activity for Alternatives C4A or C9A would cause more disruption to circulation and public service access, including temporary restrictions on ingress and egress from the parking area at Bellevue City Hall, which houses the Bellevue Police Department, but the disruption would also likely have the shortest duration of the Segment C alternatives. Construction of Alternatives C8E, C7E, or C14E might cause longer delays in access but also result in fewer roadway closures than the at-grade Segment C alternatives would. The construction of cut-and-cover tunnel sections for Alternatives C1T or C2T would cause the longest period of construction, would be the most limiting for public service access, and would have similar general disruptive impacts as *Preferred Alternative C9T*. Alternative C3T would be almost entirely bored with limited cut-and-cover construction compared with *Preferred Alternative C9T* and Alternatives C1T and C2T, resulting in fewer impacts related to disruption of circulation and public service access. As with *Preferred Alternative C9T*, tunnel construction for Alternative C1T, C2T, or C3T would require the Bellevue Fire and Police Departments to receive special training for any incidents that could occur associated with tunnel construction. This training would be developed as part of the SSMP and in coordination with the Fire/Life Safety Committee.

Alternatives crossing I-405 at NE 12th Street (i.e., Alternatives C4A, C3T, C7E, and C8E) would result in construction impacts near Overlake Hospital Medical Center and Group Health Medical Center. Any required lane closures or detours would need to be coordinated with these hospitals to maintain access for emergency medical vehicles. Coordination would also need to occur to prevent interruptions in utility service (e.g., water, electrical) to these Medic One facilities. See Section 4.15, Utilities, for further information on utility relocations and disruptions.

There would be no additional impacts or differences related to construction impacts and the connectors from the Segment B and D alternatives associated with Segment C.

Segment D

Preferred Alternative D2A would not result in any additional construction-related impacts other than those described above under Impacts Common to All Alternatives.

There would be no additional impacts other than those described above under Impacts Common to All Alternatives with the other Segment D alternatives; however, there would be differences between the alternatives in terms of levels of disruption and access. Alternative D3 would cause the greatest amount of disruption to circulation and public service access of the Segment D alternatives, because of the construction activities associated with the retained cut along NE 20th Street and 152nd Avenue NE. Alternative D5 would result in the least disruption of the Segment D alternatives, because the alternative would be located on the south side of SR 520, primarily adjacent to WSDOT right-of-way. Alternative D2E would follow the same route as *Preferred Alternative D2A* and would result in similar impacts during construction.

Segment E

Preferred Alternative E2 would not result in any additional construction-related impacts other than those described above under Impacts Common to All Alternatives. The other Segment E alternatives would result in no additional impacts other than those described above under Impacts Common to All Alternatives. Alternative E1 would likely result in slightly more disruption and access issues than Alternative E4 due to its slightly greater length.

4.14.3.4 Maintenance Facilities

Impacts during Operation

No impacts on public services are anticipated from any of the maintenance facility alternatives during operation, because these facilities are closed to public access and do not obstruct access or create new solid waste removal requirements.

Impacts during Construction

Construction of the 116th Maintenance Facility (MF1) would relocate the Bellevue Public Safety Training Center at 1828 116th Avenue NE. This facility is used by the City of Bellevue as a training facility for police and fire department staff. Sound Transit would work with the City of Bellevue to minimize the disruptive effect of this relocation. Construction of the BNSF Maintenance Facility (MF2) or the SR 520 Maintenance Facility (MF3) would not result in negative impacts on public services. Construction of the SE Redmond Maintenance Facility (MF5) could create noise and dust impacts near the Lake Washington Technical College Redmond Corporate Campus.

4.14.4 Potential Mitigation Measures

The Fire/Life Safety Committee and other Sound Transit safety and security specialists would continue to address public service issues throughout design, construction, and operation.

4.14.4.1 Operation Mitigation Measures

Some minor delays in response time might result where alternatives consist of a semi-exclusive (at-grade) trackway. Emergency vehicles might be required to go around these facilities or use other adjacent roadways. Access to fire hydrants might either require temporarily stopping light rail service or, as deemed necessary during final design, installing fire hydrants on either side of at-grade trackway. These situations would not result in an adverse impact on public services, and no mitigation would be necessary during operation.

Although the overall crime rate typically does not increase due to light rail projects, research from other systems shows that some petty crimes might occur at stations and, more likely, at park-and-ride facilities. To minimize these occurrences, Sound Transit would create and implement an SSMP and employ CPTED design principles directed at reducing crime incidents at stations and park-and-ride lots. Other measures to minimize crime would include using equipment (i.e., CCTV cameras, sealed fareboxes on ticket vending machines, and automatically sealed exits), using anti-graffiti materials, and employing security personnel. In addition, Sound Transit contracts with the County Sheriff, a private security firm, and works with local law enforcement to provide police services along the light rail system. With these public safety programs in place, there would be no need for additional mitigation measures.

4.14.4.2 Construction Mitigation Measures

During construction, several roadways would be fully or partially closed, thus limiting access and requiring detours. This might cause minor delays on emergency response times and cause detours for other public services. Sound Transit would coordinate with public service providers before and during construction to maintain reliable emergency access and alternative plans or routes to minimize delays in response times. Sound Transit would also coordinate with solid waste and recycling companies and schools should any rerouting of collection or school bus routes need to occur. Postal collection and delivery and solid waste and recycling collection would be maintained at all addresses. No additional mitigation would be required.

4.15 Utilities

4.15.1 Introduction to Resources and Regulatory Requirements

This section analyzes the short-term construction and long-term operation impacts on utility providers and systems that would serve or could be affected by the light rail system and facilities. Utility providers throughout the study area include municipal agencies, public utility districts, and private companies. The study area is defined as the area within 100 feet of the alternative routes and stations and within the project limits for staging areas and maintenance facilities.

The relationship between transportation projects and utilities within the project corridor is regulated by local policies and procedures for Seattle, Mercer Island, Bellevue, and Redmond, as well as Washington Administrative Code (WAC) 468-34 and Washington State Department of Transportation (WSDOT) policies within their right-of-way.

4.15.2 Affected Environment

Sound Transit identified existing and planned utilities in the study area. Utilities considered in this analysis include water, sanitary sewer, storm sewer, electrical power, natural gas, telephone and communications infrastructure, and petroleum products pipelines. Information on existing utilities was obtained through a database research and by contacting local municipalities and utility companies.

Although the East Link corridor would cross a number of jurisdictions, including Seattle, Mercer Island, Bellevue, and Redmond, a number of utility providers are the same in them. Common utility providers in these jurisdictions include Puget Sound Energy for natural gas, Comcast for cable television, and Qwest Communications for telephone service. A number of other companies (e.g., AT&T, Verizon, Level 3 Communications) maintain fiberoptic cables throughout the area as well. Table 4.15-1 summarizes the utility providers in each jurisdiction.

4.15.2.1 Segment A

Electricity in Seattle is provided by Seattle City Light, and electricity on Mercer Island is provided by Puget Sound Energy; Puget Sound Energy provides natural gas in both locations. In Seattle, Seattle Public Utilities manages the water, sewer, and stormwater utilities. Seattle gets 70 percent of its water from the Cedar River watershed, with the remaining 30 percent coming from the South Fork Tolt River and from groundwater wells in the Highline Well Field. Therefore, Seattle Public Utilities owns water transmission lines that go through Mercer Island, Bellevue, and Redmond. In Mercer Island, the City of Mercer Island provides water and sewer services, with water service contracted to Seattle Public Utilities and sewer service contracted to King County Wastewater.

Qwest Communications provides telephone service throughout the entire project vicinity. Telephone lines in urban areas are typically located within street right-of-way, aboveground on utility poles, or underground in duct banks, often shared with other smaller fiberoptic utilities. Several private companies (Verizon, MFS Network Technologies, Level 3 Communications and others) maintain fiberoptic cables and/or provide long-distance telecommunications services in the project vicinity. In addition, local and state agencies have networks of fiberoptics within the roadway and right-of-way for emergency and traffic uses and for roadway lighting.

4.15.2.2 Segments B, C, D, and E and Maintenance Facilities

Puget Sound Energy is the natural gas and electricity provider in Bellevue and Redmond. Electrical substations are located on the south side of Bellevue Way at 112th Avenue NE, on NE 12th Street east of 116th Avenue NE, and on 152nd Avenue NE at NE 21st Street. Puget Sound Energy intends to expand the substation on NE 12th Street before project construction begins. Major transmission lines (115 kilovolt [kV] and 230 kV) are located along 136th Place NE, 140th Avenue NE, 114th Avenue SE, 116th Avenue NE, and NE 51st Street. Seattle City Light owns major transmission lines located along 124th Avenue NE.

The Cities of Bellevue and Redmond provide water, sewer, and stormwater service within their City limits. Both cities are members of the Cascade Water Alliance, which is an association of water and sewer districts that coordinate management of the water supply for the communities of Bellevue, Kirkland, Redmond, Issaquah, Sammamish, Tukwila, Covington, and Skyway. Seattle Public Utilities also maintains water transmission lines within these segments and supplies water to these areas for the Cascade Water Alliance. Olympic Pipe Line maintains two petroleum pipelines, a 16-inch and a 20-inch, that run north-south through east Bellevue, roughly parallel to 136th Place NE.

Major utility upgrades or expansions identified in the study area include the following:

- Puget Sound Energy plans to expand the substation on NE 12th Street east of 116th Avenue NE and gas lines within the study area.
- City of Bellevue is replacing and upsizing several sewer facilities within the study area.

TABLE 4.15-1
Utility Providers in Study Area

Jurisdiction	Utility	Provider
Seattle	Gas	Puget Sound Energy
	Electricity	Seattle City Light
	Water[a] and sewer (wastewater)	Seattle Public Utilities, King County Wastewater
	Stormwater	Seattle Public Utilities
	Cable	Comcast, Broadstripe
	Communications	Qwest Communications, Verizon, others
Mercer Island	Gas	Puget Sound Energy
	Electricity	Puget Sound Energy
	Water and sewer (wastewater)	City of Mercer Island (from Seattle Public Utilities and King County Wastewater)
	Stormwater	City of Mercer Island
	Cable	Comcast
	Communications	Qwest Communications, Verizon, others
Bellevue	Gas	Puget Sound Energy
	Electricity	Puget Sound Energy
	Water and sewer (wastewater)	City of Bellevue, King County Wastewater
	Stormwater	City of Bellevue
	Cable	Comcast, Broadstripe
	Communications	Qwest Communications, Verizon, others
Redmond	Gas	Puget Sound Energy
	Electricity	Puget Sound Energy
	Water and sewer (wastewater)	City of Redmond, King County Wastewater
	Stormwater	City of Redmond
	Cable	Comcast
	Communications	Qwest Communications, Verizon, others

[a] Seattle Public Utilities owns water transmission lines east of Lake Washington in the cities of Mercer Island, Bellevue, and Redmond.

- City of Redmond plans to construct a new stormwater trunk line within the former BNSF railway right-of-way in Downtown Redmond starting in summer 2011.

These projects would require continued coordination with utility agencies.

4.15.3 Environmental Impacts

4.15.3.1 No Build Alternative

Under the No Build Alternative, no light rail improvements would be constructed in the study area. Changes in land use in the project vicinity would determine the demand for utilities with or without light rail. Typically, automobile-oriented land uses are more spread out and less dense than transit-oriented development patterns. This could lead to development of more land area, creating demand for increased utility infrastructure to cover a greater area.

4.15.3.2 Impacts during Operation

Sound Transit conducted an inventory of impacts on utilities for the East Link Project. These utilities were divided into major utilities and minor utilities, with major utilities defined as follows:

- Water mains of 16-inch diameter or greater
- Sanitary sewer force mains and gravity sewers of 16-inch diameter or greater
- Storm drains of 36-inch diameter or greater
- 115-kV and greater electrical transmission lines
- High-pressure and intermediate-pressure gas lines with a 6-inch diameter or greater
- Telephone and fiberoptic duct banks with three or more conduits
- Petroleum product pipelines

Minor utilities were not inventoried; however, information obtained on the major utilities adequately depicts the degree to which alternatives could impact various utilities and could present potential construction and/or operation impacts. According to this inventory, major utilities affected by all alternatives include storm and sanitary sewers, aboveground electric lines, underground water and natural gas mains, and underground telephone and fiberoptic lines.

As stated in the Utilities Element of the City of Bellevue's Planning and Community Development Policies, existing overhead utilities (power and communications) that require relocation as part of any project are to be relocated underground, which would apply to the utility relocations that are part of the East Link Project. The City of Redmond has a similar ordinance. For power lines, this would not apply to 115-kV and 230-kV transmission lines.

Electricity for the light rail project would be provided by Seattle City Light for the City of Seattle in Segment A and Puget Sound Energy for Mercer Island and in Segments B, C, D, and E. Puget Sound Energy also provides electric services to portions of the I-90 bridge. As discussed in Section 4.10, Energy Impacts, operating the light rail system would increase electricity demand in the study area but would reduce overall transportation energy consumption through reduced automobile use. The energy needed to power the East Link light rail vehicles would not require Seattle City Light or Puget Sound Energy to seek additional energy resources. Availability of power supply to each of the project's traction power substations might, in some cases, require that additional distribution lines to the substation be constructed. The specific needs will not be known until further coordination with Seattle City Light and Puget Sound Energy occurs during final design.

Under Sound Transit's Sustainability Initiative, adopted in 2007, Sound Transit would integrate efficient operating practices at existing and new facilities and use equipment to reduce energy and water demand and recycle water. Implementing these and other sustainability initiatives would reduce consumption and demand on utilities. The Sustainability Initiative is further discussed in Section 4.10, Energy.

The proposed light rail line would use up to four-car electric trains operating on direct-current (DC) power taken from the 26-kV electric distribution facilities. Lighting installed at stations and safety lighting along the routes, the maintenance facilities, parking areas, and other light rail facilities would increase electrical demand. The maximum peak demand for all alternatives would be similar, at approximately 245 million British thermal units (Btu) per day. This represents less than 0.1 percent of the total 2006 generation for Seattle City Light and Puget Sound Energy combined.

To distribute power along the corridor, traction power substations (TPSS) would be located approximately every 2 miles that would provide power to the overhead contact system that powers the light rail vehicles. These stations would be powered by 26-kV electric lines connecting to the nearest power pole. In Segment C, alternatives that require tunnels would have greater electricity requirements, and for all segments, longer alternatives would require more electricity than shorter ones. For further information on energy demands of the project and any additional infrastructure required, see Section 4.10, Energy Impacts. Stray electrical current from the light rail's traction power electrical system can cause damage to nearby utilities if not properly controlled. Section 4.13, Electromagnetic Fields, addresses indirect effects of stray currents from light rail vehicles.

No substantial differences among alternatives are expected in long-term utility service within any of the segments. Major service disruptions to utility customers during light rail repair and maintenance operations are unlikely. The light rail route would be located so that access to utilities for maintenance and repair could be maintained. In some cases, sewer holes, pipes, vaults, and other access points might have to be relocated. During design, Sound Transit would work closely with utility providers to provide required access to these utilities and any relocated sewer holes and vaults, utility mains, fire hydrants, and other features.

Maintenance Facilities

There are no impacts on major utilities from maintenance facilities during operation. At all potential sites, the proposed maintenance facilities would require new water supply connections for vehicle washing and other uses. Approximately 95 percent of maintenance base water demand is for vehicle washing. Vehicle washwater would be recycled. The additional demand would not greatly affect the water providers' existing and projected water supplies. Similarly, water demand would not likely compromise flow for fire protection, but demand should be coordinated with fire departments and water suppliers in order to avoid impacts.

The maintenance facilities drainage system would be designed to filter and recycle a high percentage of the wash and rinse water. Solids, oils, soaps, and other contaminants would be filtered, settled to a sludge tank, and periodically hauled for disposal in accordance with applicable regulations. Some disposal to the local sanitary sewer system would be expected from the recycled, filtered washwater. The water discharged to the sanitary sewer system would be disposed of according to local and state regulations. For the potential sites, existing sewer lines on adjacent streets are available for sewer connections. Any needed stormwater detention facilities and infrastructure to collect storm- and wastewater would connect to both the existing sewer system and stormwater conveyances. Impacts on stormwater are discussed in Section 4.9, Water Resources.

4.15.3.3 Impacts during Construction

Impacts Common to All Build Alternatives

Sound Transit identified utility conflicts for each alternative either where underground utilities would be within the project limits or where the project route and existing utilities would intersect. The goals of identifying these conflicts are to plan for relocating the utilities during construction and, thus, remove conflicts with project construction; to prevent disturbing the route during future maintenance of underground utilities; to keep the profile—whether underground, surface, or elevated—clear of the minimum required distance from overhead utilities; and to account for the relocation costs.

Potential impacts during construction include relocating utility poles supporting overhead lines; constructing new distribution lines to provide power to substations; relocating underground utilities from under the alternatives, station areas, and maintenance facility sites (particularly at-grade segments constructed in road right-of-way); and inspecting, repairing, and encasing underground utilities at track crossings. In some cases, aboveground utilities located on poles could be relocated to taller poles or a different type of pole. Access to underground utilities, such as sewer holes or vaults, for maintenance activities could be affected depending on the location of light rail facilities. In some cases, these access points might need to be relocated. Relocating water mains could also affect access to and use of fire hydrants. In some cases, establishing a parallel water main to avoid utility lines crossing under the trackway might be considered. Some of these impacts might be substantial to some utility service providers in terms of relocation costs incurred, staff time and resources, and temporary loss of existing access to utilities. Relocation approaches and associated costs would be evaluated by Sound Transit on a case-by-case basis. Generally, the terms of a private utility's franchise agreement would be applied to determine the rights of the private utility in the public right-of-way and the responsibility for relocation costs. For public utilities, Sound Transit would seek to establish formal agreements with the public utility, and the relocation costs would be allocated pursuant to local ordinances or codes.

Typically, water lines and high-pressure gas mains are located about 3 to 6 feet underground and sewer pipes located 6 or more feet below the surface. Smaller pipes, fiberoptic cables, telephone lines, and other utilities are often buried less than 3 feet deep. Water, sewer, and storm drain pipelines typically run parallel beneath streets, placed in various locations ranging from the center to the roadway periphery, while fiberoptic cables, telephone lines, underground electrical conduits, and smaller pipes are often located beneath sidewalks. These utilities might or might not be affected during construction, depending on their depth, material composition, the excavation limits, exact location of the proposed route, and other factors. However, most underground utilities crossed by the proposed route are located within approximately 6 feet of the surface and within 35 feet of segment columns. Underground utilities would be relocated or otherwise protected to allow for excavation and to minimize potential load impacts on existing utilities from the weight of the light rail vehicles.

Generally, cut-and-cover construction, followed by at-grade construction, would have the greatest impacts on utility infrastructure, because these segments would relocate more underground pipes and aboveground utility poles for trackways, stations, and right-of-way curb and sidewalk acquisition. At-grade routes and cut-and-cover stations could require relocating longer sections of underground pipes and cables in street rights-of-way.

In most cases where an at-grade profile crosses an underground utility, a split casing could be installed, which is a steel pipe that serves as casing around the utility line or pipe, allowing the utility company to remove or install utilities at that location in the future without disturbing the ground above. Underground utilities, located within public road rights-of-way, parallel to and near or under the alternative would be moved to a different location within the right-of-way. As much as possible, piers for elevated guideways would be located to avoid conflicting with underground utilities. Retained-cut profiles could accommodate underground utilities that are under cross streets, but utilities outside of cross streets may present design problems. Bored tunnel profiles generally avoid utility conflicts except at stations, where temporary conflicts with underground utilities would occur during cut-and-cover construction of the station. For overhead electric lines, conflicts could occur where elevated guideways either run directly underneath the lines or where they cross the lines, which would require raising the lines to go over the overhead catenary system at the required minimum distance of 35 feet from the top of rail for 115-kV lines and 37 feet for 230-kV lines.

Disruptions to utility service during utility relocations would likely be minimal because temporary connections to customers would typically be established before relocating utility conveyances. However, inadvertent damage to underground utilities could occur during construction if utility locations are uncertain or misidentified. Although such incidents do not occur frequently, the numerous relocations required during project construction under any alternative make accidents more likely. Such accidents could temporarily affect service to customers served by the affected utility. Efforts to minimize impacts would include potholing and preconstruction surveys to identify utility locations and outreach to customers to inform them regarding potential service disruptions. Sound Transit would also coordinate with utility providers to establish replacement procedures and standards of facilities as applicable.

Exhibits 4.15-1 through 4.15-4 show areas of major utility conflicts for Segments B, C, D, and E. Table 4.15-2 summarizes the conflicts for each alternative. Where utilities would be directly under or above the project limits, the length of the relocation is provided. Ranges are provided in Segments C and D where different design options would result in varying impacts for the same utilities. Where utilities would intersect with an alternative, the number of crossings is identified because the length of the relocation has not yet been determined, but it would be determined during final design. For many underground intersecting utilities, only a split casing would need to be installed.

Segment A

No utility conflicts are anticipated with *Preferred Interstate 90 Alternative (A1)*, and no utilities would need to be relocated. Utilities presently run underneath or along the side of the I-90 bridge decks and are accessed by the utility companies from underneath. East Link Project construction would not relocate any of these utilities, and future maintenance of these utilities would not disturb light rail operation.

Segment B

Within Segment B, the Bellevue Way Alternative (B1) would require the most utility relocations, and the BNSF Alternative (B7) would require the fewest. *Preferred 112th SE Modified Alternative (B2M)* and 112th SE At-Grade (B2A), 112th SE Elevated (B2E), and 112th SE Bypass (B3) Alternatives would require similar utility relocations.

For *Preferred Alternative B2M*, approximately 500 feet of sanitary sewer line owned by King County would be impacted by the roadway work along Bellevue Way; 300 feet of this line is located in the South Bellevue Park-and-Ride. Puget Sound Energy power transmission lines would conflict with the elevated track where they cross Bellevue Way near SE 30th Street and 112th Avenue SE.

With connections to *Preferred Alternative C11A*, 900 feet of a Qwest Communications conduit located along 112th Avenue SE between SE 15th and SE 8th Streets would be relocated; most of this relocation would result from the construction associated with widening 112th Avenue SE. With the connection to *Preferred Alternative C9T*, 200 feet of a Qwest communications conduit, and associated cabinets would be relocated at the intersection of 112th Avenue SE and SE 15th Street. With a connection to *Preferred Alternative C11A*, 800 feet of a PSE gas line located on the east side of 112th Avenue SE between SE 8th and SE 6th Streets would be relocated; most of this relocation would result from the construction associated with widening 112th Avenue SE. With the connection to *Preferred Alternative C9T*, 500 feet of a PSE gas line located on the east side of 112th Avenue SE between SE 8th and the Segment C boundary would be relocated.

For *Preferred Alternative B2M* to *Preferred Alternative C11A*, a storm drain on 112th Avenue SE, south of SE 15th Street, owned by the City of Bellevue, would be relocated due to track excavation. When connecting to *Preferred Alternative C9T*, this same storm drain would be relocated as well as the east outlet of the storm drain. When connecting to *Preferred Alternative C11A*, along 112th Avenue SE between SE 15th and SE 8th Streets, more than 1,100 feet of sanitary sewer owned by the City of Bellevue would be relocated. When connecting to *Preferred Alternative C9T*, 600 feet of this same sanitary sewer line would be relocated.

At the intersection of SE 8th Street and 112th Avenue SE, with either connection to *Preferred Alternative C11A* or *C9T*, a fiberoptic vault, conduit, and cable owned by multiple agencies would be relocated. Also at this intersection, with either connection to Segment C, segments of Comcast cable would be relocated due to potential track excavation impacts to the duct banks. A City of Bellevue sewer pump station is currently located in the 1300 block of 112th Avenue SE, although the City plans to relocate and expand this facility as part of their Capital Investment Program (CIP).

Utility Conflicts
Segment E
East Link Project

TABLE 4.15-2
Utility Conflict Summary Approximate Length of Relocations and Number of Crossings

Alternative		Power Line	Water Line	Sanitary Sewer Line	Gas Line	Communications[a]	Storm Drain
Segment A, Interstate 90							
Preferred Interstate 90 Alternative (A1)		None	None	None	None	None	None
Segment B, South Bellevue							
Preferred 112th SE Modified Alternative (B2M)	To *Preferred Alternative C11A*	2 crossings	None	1,200 feet, 2 crossings	800 feet	1,300 feet, 2 crossings	1 crossing
	To *Preferred Alternative C9T*	2 crossings	None	500 feet, 2 crossings	500 feet	7000 feet, 2 crossings	100 feet
Bellevue Way Alternative (B1)		100 feet, 3 crossings	None	5,200 feet	None	4,200 feet, 1 crossing	None
112th SE At-Grade Alternative (B2A)		100 feet, 2 crossings	None	7,300 feet	None	600 feet	None
112th SE Elevated Alternative (B2E)		100 feet, 1 crossing	None	3,400 feet	None	600 feet	None
112th SE Bypass Alternative (B3)		100 feet, 1 crossing	None	3,400 feet	None	600 feet	None
B3 - 114th Extension Design Option		300 feet, 1 crossing	None	3,500 feet, 1 crossing	None	700 feet, 1 crossing	100 feet
BNSF Alternative (B7)		3 crossings	None	1 crossing	None	None	None
Segment C, Downtown Bellevue							
Preferred 108th NE At-Grade Alternative (C11A)		300 to 600 feet	None	2,400 to 2,500 feet, 2 crossings	1,100 to 1,600 feet, 2 crossings	6,200 to 8,000 feet	100 feet
Preferred 110th NE Tunnel Alternative (C9T)[b]		1 crossing (from Alternative B7 only)	None	2,100 feet, 1 crossing (from Alternatives B3 and B7 only)	2,500 to 3.400 feet	10,400 to 12,300 feet	100 feet
Bellevue Way Tunnel Alternative (C1T)		1 crossing	None	2,700 feet, 3 crossings	2 crossings	2,100 feet, 2 crossings	300 feet, 2 crossings
106th NE Tunnel Alternative (C2T)		200 feet (from Alternative B7 only), 1 crossing	None	2,100 to 2,600, 1 or 2 crossings	1 or 2 crossings	1 crossing	1,500 to 1,600 feet
108th NE Tunnel Alternative (C3T)		4,100 feet (from Alternative B7 only)	None	0 to 500 feet, 1 or 2 crossings	500 feet, 0 or 1 crossing	300 feet, 1 crossing	None
Couplet Alternative (C4A)		300 feet (from Alternative B7 only)	None	0 to 1,100 feet, 1 or 2 crossings	4,600 to 5,000 feet, 3 or 4 crossings	4,800 feet, 1 crossing	700 feet, 1 crossing
112th NE Elevated Alternative (C7E)		300 feet (from Alternative B7 only)	None	1,000 feet (from Alternative B2A only)	0 to 400 feet	None	None

TABLE 4.15-2 CONTINUED
Utility Conflict Summary Approximate Length of Relocations and Number of Crossings

Alternative	Power Line	Water Line	Sanitary Sewer Line	Gas Line	Communications[a]	Storm Drain
110th NE Elevated Alternative (C8E)	1,700 feet (from Alternative B7 only)	None	None	700 feet	None	690 feet
110th NE At-Grade Alternative (C9A)	300 feet 200 feet, 1 crossing (from Alternative B7 only)	None	2,200 feet	1,200 feet	7,700 feet	100 feet
114th NE Elevated Alternative (C14E)	1,500 feet	None	None	None	None	None
Segment D, Bel-Red/Overlake						
Preferred NE 16th At-Grade Alternative (D2A)[c]	2,900 feet	100 feet	900 feet	900 feet	4,600 feet	1,000 feet
D2A - NE 24th Design Option	3,300 feet	100 feet	1,000 feet, 1 crossing	800 feet, 3 crossings	8,200 feet	1,500 feet
NE 16th Elevated Alternative (D2E)	2,100 feet, 4 crossings	1 crossing	Up to 1 crossing	None	1 crossing	1 crossing
NE 20th Alternative (D3)	1 crossing	2 crossings	None	4 crossings	1 crossing	100 feet, 3 crossings
SR 520 Alternative (D5)	3 crossings	2 crossings	None	1 crossing	1 crossing	1 crossing
Segment E, Downtown Redmond						
Preferred Marymoor Alternative (E2)	None	None	1,100 feet, 1 crossing	1,100 feet, 2 crossings	6 crossings	None
E2 - Redmond Transit Center Design Option	None	None	1,100 feet, 1 crossing	1,100 feet, 3 crossings	6 crossings	None
Redmond Way Alternative (E1)	None	None	1,000 feet	1,100 feet, 1 crossing	6 crossings	None
Leary Way Alternative (E4)	None	None	1,000 feet	800 feet	6 crossings	None

[a] Communication utilities include fiberoptic, telephone, and cable.

[b] The C9T - East Main Station Design Option connecting from *Preferred Alternative B2M* would not result in a change to impacts on either *Preferred Alternative C9T* or *B2M*.

[c] Impacts for D2A - 120th Station Design Option would not vary from those of *Preferred Alternative D2A*.

Note: As-built utility data were used to determine impacts of major utilities; some segments in as-built data might not represent full segment and will be finalized with field check. Length of relocations is rounded.

The pump station would be relocated to a site that does not conflict with the light rail route before East Link construction begins. Once the pump station has been relocated, sewer lines along 112th Avenue SE would be installed as part of the East Central Business District (CBD) Sewer Trunkline Improvements Project.

Similar to *Preferred Alternative B2M,* Alternative B1 would relocate an existing 115-kV electrical transmission line pole and approximately 100 feet of electrical line owned by Puget Sound Energy near vicinity of Bellevue Way SE at 112th Avenue SE. Also, approximately 5,200 feet of sewer lines and sewer holes owned by King County Wastewater would be relocated along Bellevue Way. Communication ducts owned by Qwest Communications are also present along the west side of Bellevue Way SE, and approximately 4,200 feet would be relocated. A conflict would also occur with a Qwest Communication duct that crosses under Bellevue Way SE north of SE 30th Street, where the duct would be relocated deeper below the roadway.

With Alternative B2A, overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative where they cross Bellevue Way near SE 30th Street and would be raised. Approximately 3,800 feet of 27-inch sewer lines and sewer holes owned by King County Wastewater would be relocated under Bellevue Way where a conflict would occur in front of Mercer Slough Nature Park. Approximately 1,900 feet of 14-inch sewer force main owned by the City of Bellevue would be relocated under 112th Avenue SE between Bellevue Way and SE 15th Street. Approximately 1,650 feet of sewer pipes under 112th Avenue SE between SE 15th Street and 11th Place SE would also need to be relocated.

With Alternative B2E, overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative and would be raised where they cross Bellevue Way near SE 30th Street and just before 112th Avenue SE. Approximately 1,500 feet of 27-inch sewer lines and sewer holes owned by King County Wastewater and 1,880 feet of sewer lines owned by the City of Bellevue would be relocated under Bellevue Way where a conflict would occur in front of Mercer Slough Nature Park.

With Alternative B3, overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative where they cross Bellevue Way near SE 30th Street and would be raised. Approximately 450 feet of sewer lines and sewer holes owned by King County Wastewater would be relocated under Bellevue Way SE where a conflict would occur in front of Mercer Slough Nature Park. Approximately 3,000 feet of sewer force main owned by the City of Bellevue would be relocated under 112th Avenue NE between Bellevue Way and SE 15th Street.

The utility impacts with the B3 - 114th Extension Design Option would be similar to those for Alternative B3 between *Preferred Alternative A1* and the Winters House along Bellevue Way SE. Just north of the Winters House, approximately 100 feet of a Qwest Communications duct bank and associated cabinets and 100 feet of a City of Bellevue-owned sanitary sewer line would be relocated due to track excavation. Where the elevated light rail track crosses 114th Avenue SE, more than 100 feet of a 115-kV overhead power line owned by Puget Sound Energy would be relocated.

Alternative B7, overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative where they cross 114th Avenue SE at three different locations. This would also be required for all Segment C alternatives that connect to Alternative B7.

Segment C

All Segment C alternatives would require extensive utility relocation, many related to cut-and-cover construction of tunnels or stations. Alternatives C7E and C14E are the only alternatives with the potential for few or no conflicts. No water utility lines would be impacted by any of the Segment C alternatives. Where conflicts occur in cut-and-cover construction areas, the utilities would be worked around or temporarily relocated. Bored tunnels would be deep enough to avoid utility conflicts. For tunnel construction, Sound Transit would use industry-standard methods to mitigate the impacts of soil settlement on underground utilities and special infrastructure concerns.

Generally, unless otherwise noted, utilities impacted by *Preferred 108th NE At-Grade Alternative (C11A)* are due to track excavation and the duct banks or pipes work. Along 112th Avenue SE between the end of Segment B and just north of SE 4th Street, approximately 2,000 feet of fiberoptic line owned by City of Bellevue and Integra/Verizon Business would be relocated. West of the 108th Station, 300 feet of Qwest Communication line would be relocated.

Between the beginning of *Preferred Alternative C11A* and SE 6th Street along 112th Avenue SE, more than 400 feet of City of Bellevue sanitary sewer line would be relocated. Beginning at the intersection of 108th Avenue and NE 2nd Street, gas pipe (500 feet), communications line (more than 800 feet), fiberoptic line (more than 1,500 feet), and cable line (800 feet) utilities would be relocated. At the intersection of

NE 4th Street and 108th Avenue, more than 1,000 feet of fiberoptic network and 200 feet of City of Bellevue sanitary sewer would be relocated because track excavation might impact the duct banks and pipes in this area.

North of NE 4th Street, adjacent to the proposed staging area, 600 feet of Puget Sound Energy gas line and 400 feet of Qwest Communications line would be relocated. Along NE 6th Street, between 110th and 112th Avenues NE, 800 feet of Qwest Communications telephone line, 600 feet of fiberoptic network (owned by multiple agencies, and 200 feet of Puget Sound Energy gas line would be relocated.

East of the Bellevue Transit Center Station, several utilities at the intersection of NE 6th Street and 110th Avenue NE would be relocated due to track excavation; these utilities include a Qwest Communications line, a Puget Sound Energy gas pipe, and a fiberoptic duct banks. Where the elevated track crosses 116th Avenue NE, overhead power lines owned by Puget Sound Energy would be relocated to prevent them from interfering with the elevated guideway.

Beginning at the south end of the Hospital Station, 2,000 feet of a sanitary sewer owned by King County would be relocated due to load restrictions. Adjacent to the Hospital Station, a City of Bellevue storm drain and pipes would be relocated due construction impacts to the catch basin and pipes underneath the station.

During tunnel construction for *Preferred Alternative C9T*, utilities located above the tunnel alignment along 110th Avenue NE between Main and NE 6th Streets would be temporarily supported in place and worked around. These utilities include more than 4,700 feet of telephone line owned by Qwest Communications, more than 3,000 feet of fiberoptic line owned by multiple agencies, 1,300 feet of Comcast cable, more than 2,500 feet of Puget Sound Energy gas line, and more than 100 feet of City of Bellevue sanitary sewer line.

Near the intersection of 112th Avenue SE and SE 6th Street, 900 feet of Puget Sound Energy gas line would be relocated due to potential track excavation impacts to the pipe. Also near this intersection, more than 1,500 feet of fiberoptic line, 200 feet of City of Bellevue sanitary sewer, and 300 feet of Qwest Communications line would be relocated.

More than 1,200 feet of Qwest Communications telephone line along NE 6th Street would be relocated due to the potential track excavation impacts to the duct bank. Due to load restrictions, more than 2,000 feet of King County sanitary sewer along the former BNSF Railway corridor near the Hospital Station would be relocated. Similar to *Preferred Alternative C11A*, constructing the Hospital Station would relocate a storm drain catch basin and 50 feet of pipes underneath the station.

With Alternative C1T, utility conflicts would occur in cut-and-cover areas where City of Bellevue storm sewers run under Bellevue Way from SE 6th Street to NE 2nd Street and Qwest Communications ducts run under Bellevue Way from SE 6th Street to Main Street. A Puget Sound Energy natural gas line and Qwest Communications duct would also conflict at the crossing of 108th Avenue NE. A 54-inch concrete storm drain pipe would conflict where this alternative crosses 106th Avenue NE, as would an 18-inch sanitary sewer pipe where it crosses 112th Avenue NE. Overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative where it becomes elevated and would be raised across 116th Avenue NE. An underground 6-inch gas line that runs under 108th Avenue NE would conflict with the proposed Bellevue Transit Center Station, and the alternative would cross a 12-inch line in 110th Avenue NE at NE 6th Street.

With Alternative C2T, when connected to Alternative B3, B3 - 114th Extension Design Option, or Alternative B7, a conflict would occur with a sanitary sewer crossing and a 12-inch gas line crossing at 112th Avenue SE, coming out of the East Main Station. A 24-inch sanitary sewer line would conflict in the cut-and-cover area where the sewer line crosses 112th Avenue SE for connections to Alternative B3, B3 - 114th Design Option, B7, or B2A. City of Bellevue sanitary and storm sewers also run under 106th Avenue NE and would be worked around during cut-and-cover construction. A City of Bellevue 72-inch storm sewer line would also conflict with the cut-and-cover along NE 6th Street. Overhead 115-kV electrical lines owned by Puget Sound Energy would conflict with this alternative where it becomes elevated and would be raised across 116th Avenue NE. Underground 6-inch gas lines that run under 108th Avenue NE would conflict with the proposed Bellevue Transit Center Station and the alternative would cross a 12-inch line in 110th Avenue NE at NE 6th Street.

With Alternative C3T, cut-and-cover construction would conflict with a 24-inch sanitary sewer line where the sewer line crosses 112th Avenue SE for connections to Alternative B3, B3 – 114th Design Option, B2A, or B7. A Puget Sound Energy natural gas line and Qwest Communications ducts would conflict with the proposed station on 108th Avenue NE. Qwest

Communications ducts would again need to be worked around on 108th Avenue NE just south of NE 12th Street, as well as under the crossing of NE 12th Street. Six-inch gas lines located along NE 12th Street and 112th Avenue SE would be relocated due to potential conflicts with the light rail alignment. A conflict with a 12-inch natural gas line would occur if connecting to Alternative B3, B3 – 114th Design Option, or B7 at 112th Avenue SE near the East Main Station. For Alternative C3T, the 6-inch natural gas line and Qwest Communications fiberoptic lines that run under 108th Avenue NE would not conflict with the alternative because the tunnel could be bored beneath these lines, except at the Bellevue Transit Center Station, which would be cut-and-cover.

With Alternative C4A, a 24-inch sanitary sewer line would conflict where the sewer line runs under 112th Avenue SE for 1,100 feet, as well as where the alternative would cross a King County sanitary sewer line at NE 4th Street. The existing storm detention system under 110th Avenue NE would be relocated for approximately 700 feet. A conflict would occur with a Puget Sound Energy natural gas line where it crosses NE 10th Street, and approximately 4,600 feet would be relocated under 108th Avenue NE. An additional 400 feet of a 12-inch gas line would be relocated between SE 6th and SE 4th Streets when connecting to Alternative B2A, and a conflict with the same gas line would occur if connecting to Alternative B3, B3 - 114th Design Option, or B7 at 112th Avenue SE near the East Main Station. Six-inch gas lines located along NE 12th Street, 112th Avenue NE, and NE 8th Street would also be relocated due to potential conflicts with the light rail alignment. Another conflict with a Puget Sound Energy gas line would occur at 110th Avenue NE (between NE 10th and NE 2nd Street). Approximately 4,800 feet of Qwest Communications fiberoptic ducts would be relocated under 108th Avenue NE so they would not be directly under the westbound couplet route.

With Alternative C7E, a conflict would occur with a Puget Sound Energy natural gas line where it crosses NE 10th Street. If this alternative were to connect with Alternative B2A, then a 24-inch sanitary sewer line would conflict where the sewer line parallels 112th Avenue SE for approximately 900 feet north of SE 6th Street, and a 12-inch natural gas line would be relocated for approximately 400 feet north of SE 6th Street. A conflict with the same gas line would occur if connecting to Alternative B3, B3 – 114th Design Option, or B7 at 112th Avenue SE near the East Main Station.

With Alternative C8E, the existing storm detention system under 110th Avenue NE would be relocated for approximately 700 feet because it would conflict with the project limits. Approximately 700 feet of a 12-inch gas line would be relocated between NE 8th and NE 10th Streets, and approximately 1,700 feet of overhead electric lines would be relocated if this alternative were to connect with Alternative B7 or B3 – 114th Design Option. A conflict with the same gas line would occur at 112th Avenue SE near the East Main Station.

With Alternative C9A, along 110th Avenue NE between Main and NE 6th Streets, more than 3,000 feet of Qwest Communication line would be relocated due to impacts to duct banks from track excavation. Additional communications line along NE 6th Street between 110th and 112th Avenues NE would be relocated. More than 3,500 feet of fiberoptic networks located between Main and NE 6th Streets along 110th Avenue NE, owned by multiple agencies, would be relocated due to impacts to the duct bank located under the proposed track. Along 110th Avenue NE, between NE 2nd and NE 6th Streets, more than 1,200 feet of Puget Sound Energy gas line would be relocated due to track excavation impacts. In the former BNSF Railway corridor, 2,000 feet of King County sanitary sewer line would be relocated near SE 8th Street. Additional sanitary sewer line at the intersection of 110th Avenue NE and NE 4th Street would be relocated. Sanitary sewer would be relocated for Alternative C9A due to duct bank impacts from track excavation or load restrictions. Comcast cable would be relocated at the intersections of 110th Avenue NE and Main Street and 110th Avenue NE and NE 2nd Street due to track excavation impacts to duct banks. Where the track crosses 116th Avenue NE, a segment of a Puget Sound Energy overhead power line would be relocated due to the conflict with the elevated track. With a connection to Alternative B7 or B3 – 114th Extension Design Option, a segment of a Puget Sound Energy overhead power line would be relocated due conflicts with the elevated track south of SE 6th Street along 112th Avenue SE. With connections to Alternative B3, no major utility impacts would occur.

With Alternative C14E, the only major utilities that would be impacted are overhead power lines owned by Puget Sound Energy. These impacts would be where the elevated light rail track would conflict with overhead power lines. Along 114th Avenue SE, beginning at SE 6th Street, 200 feet of 115-kV Puget Sound Energy overhead power lines would be relocated. Along 114th Avenue NE, between Main and NE 2nd Streets, more than 1,000 feet of 115-kV overhead power lines would be relocated. Additional power lines would be relocated where Alternative C14E crosses 116th Avenue NE.

Segment D

Although all Segment D alternatives would require extensive utility relocations, Alternative D3 would present the greatest challenges for utility relocations because of the amount of retained cuts. For all alternatives, a City of Redmond stormwater vault in the southwest quadrant of the NE 40th Street and 156th Avenue NE intersection would be beneath the proposed alternative and would be modified to support the weight of the rail system. With *Preferred NE 16th At-Grade Alternative (D2A)*, west of the 120th Station, more than 300 feet of fiberoptic line would be relocated because the duct bank would potentially be impacted from track excavation. Where the track crosses 124th Avenue NE, a section of a Puget Sound Energy gas pipe and Qwest Communications line would be relocated. Between 124th Avenue NE and the 130th Station, 900 feet of sanitary sewer and associated sewer holes owned by King County would be relocated. At the intersection of 132nd Avenue NE and NE 16th Street, sections of Comcast cable line, Qwest Communications line, and City of Bellevue storm drains would be relocated due to potential track excavation impacts. A storm drain sewer hole would also be relocated. At the intersection of 134th Avenue NE and NE 16th Street, 100 feet of City of Bellevue storm drain and associated sewer holes would be relocated.

Where the alignment runs at-grade along 136th Place NE to NE 20th Street, Puget Sound Energy would replace the towers supporting the power lines due to potential conflict with the light rail overhead power lines. Along 136th Place NE between NE 16th and NE 20th Streets, more than 1,800 feet of Qwest Communications fiberoptic line and a vault would be relocated. At the intersection of NE 20th Street and 136th Place NE, a fiberoptic line and storm drain would be relocated due to potential impacts from track excavation.

The *Preferred Alternative D2A* elevated guideway would be too close to elevated 115-kV overhead power lines owned by Puget Sound Energy, and the power lines would be reinstalled on higher steel poles where the route crosses 140th Avenue NE. Additional Puget Sound Energy overhead power lines near NE 24th Street would be relocated due to potential conflict with the overhead track power lines.

North of the NE 36th Street SR 520 overpass, a Microsoft fiberoptic line, Qwest Communications line, and City of Redmond water line would be relocated because track excavation could impact the duct banks and pipes. North of the Overlake Village Station at 152nd Avenue NE and SR 520, a City of Redmond storm drain pipe would be relocated. This alternative would also conflict with two petroleum pipelines owned by Olympic Pipe Line, and split casings would be installed around these pipes.

With the D2A - NE 24th Design Option, major utility impacts would be similar to *Preferred Alternative D2A* between NE 12th and NE 24th Streets and between 152nd Avenue NE and the Overlake Transit Center Station. Along 24th Street, 900 feet of Puget Sound Energy overhead power lines would be relocated due to conflicts with the elevated track. Also along NE 24th Street, more than 800 feet of Qwest Communications line and 400 feet of City of Bellevue storm drain would be relocated. This communication line and storm drain is located underneath and parallel to the tracks and would be relocated to avoid the columns. Along 152nd Avenue NE north of the Overlake Village Station, more than 2,800 feet of fiberoptic and telephone line owned by multiple companies, would be relocated due to potential track excavation impacts to the duct banks. At the end of 152nd Avenue NE, at SR 520, a sanitary sewer catch basin and a storm drain pipe and catch basin would be relocated due to potential track excavation impacts.

For Alternatives D2E, D3, and D5, two overhead transmission lines would be relocated to avoid conflicts with the construction of Segment D alternatives connecting from Alternative C3T, C4A, C7E, or C8E. With Alternative D2E, for the light rail crossings at 124th Avenue NE, 134th Avenue NE, 136th Place NE, and 140th Avenue NE, electrical overhead power lines would conflict with the elevated guideway. The towers supporting these lines would be raised or replaced in this area. The alternative would also conflict with overhead lines along NE 24th Street near 148th Avenue NE, which would require raising these lines for 2,100 feet.

With Alternative D3, the westbound trackway running along NE 16th Street near 134th Avenue NE and between SR 520 and Microsoft Road would be located over a 36-inch stormwater pipe owned by the City of Bellevue that would be relocated to the north. A 48-inch City of Redmond storm drain crosses this alternative under NE 20th Street where the guideway would be in a retained cut, and the storm drain would be redesigned to accommodate this cut. An 8-inch gas line under 148th Avenue NE and a 6-inch gas line under NE 24th Street would conflict with the retained cut under this road but would be accommodated in the road crossings over these cuts. This alternative would also conflict with two petroleum pipelines owned by Olympic Pipe Line, and split casings would be installed around these pipes. Similar to *Preferred Alternative D2A*, Puget Sound Energy towers along 140th Avenue NE and 136th Place NE would be relocated, as well as towers along 124th Avenue NE. A conflict would also occur between NE 20th and NE 24th Streets where the Interlaken Substation is located on the east side of the road. Underground feeders running north and south from this substation on 152nd Avenue NE would need to be relocated.

With Alternative D5 at 124th Avenue NE, the elevated guideway would conflict with 230-kV electrical overhead transmission lines that run north-south. Conflicts with 115-kV electrical overhead transmission lines would occur at 140th Avenue NE south of NE 24th Street. The towers supporting these lines would be raised or replaced in this area. Conflicts with electric transmission lines also would occur on the south side of NE 24th Street west of 148th Avenue NE. A natural gas line also owned by Puget Sound Energy crosses under NE 24th Street east of 148th Avenue NE and would be relocated beneath the retained cut. A 20-inch water line that runs under SR 520 at NE 36th Street would be relocated under the retained cut. This alternative would also conflict with two petroleum pipelines owned by Olympic Pipe Line, and split casings would be installed around these pipes.

Segment E

For all Segment E alternatives, telephone and fiberoptic conduits owned by Verizon would be relocated where they would conflict with the retained cuts at NE 51st and NE 60th Streets, as would communications conduits owned by Level 3 Communications at NE 60th Street. All alternatives would have sewer, gas, and communications conflicts that are similar.

With *Preferred Alternative E2*, on Redmond Way under the SR 520 crossing, 1,100 feet of a King County Wastewater 42-inch sewer line would be relocated so that it would not be below the trackway. Between Leary Way and 166th Avenue NE, 1,100 feet of an 8-inch gas line owned by Puget Sound Energy would be relocated so that it would not be below the trackway.

The E2 - Redmond Transit Center Design Option would have similar impacts as the *Preferred Alternative E2* up to where 161st Avenue NE meets the former BNSF Railway. At the Redmond Way and NE 80th Street intersection, a Puget Sound Energy 6-inch gas line would be relocated due to its proximity to the alignment.

With Alternative E1, a Verizon/MCI communications vault is located beneath the alternative where it would cross 170th Avenue NE, and would be relocated. An 8-inch natural gas line runs under the trackway for approximately 1,100 feet east between Leary Way and 166th Avenue NE. This gas line would be installed in a casing or relocated out of the project limits. A 42-inch City of Redmond storm sewer would also be relocated for approximately 1,000 feet from 170th Avenue NE to Bear Creek.

With Alternative E4, beneath the trackway in the former BNSF Railway corridor between Leary Way and 166th Avenue NE, approximately 800 feet of an 8-inch gas line owned by Puget Sound Energy would be relocated so that it would not be below the guideway. An 8-inch Puget Sound Energy gas line near the Leary Way and NE 76th Street intersection would also be relocated. Beneath the former BNSF Railway corridor between SR 520 and 170th Avenue NE, approximately 1,000 feet of a 42-inch sanitary sewer owned by King County would be relocated so that it would not be below the guideway. A Verizon/MCI communications vault is located beneath the route where it would cross 170th Avenue NE. This vault would be relocated.

The City of Redmond plans to locate a stormwater pipe and trail within the former BNSF Railway corridor in downtown Redmond, while also accommodating regional utilities and infrastructure, including Sound Transit's light rail project. Corridor space constraints could require that light rail be shifted to accommodate the stormwater pipe and trail. If this occurs for any of the Segment E alternatives, additional utility relocations may be required.

Maintenance Facilities

No impacts on utilities are anticipated during construction of any of the maintenance facilities.

4.15.4 Potential Mitigation Measures

No adverse impacts on utilities during light rail operation are anticipated; therefore, no mitigation is proposed. The project includes implementing design measures and coordinating with utility providers and the public to minimize impacts on utilities during light rail construction. These measures include potholing and preconstruction surveys to identify utility locations. Sound Transit would continue to work with utility providers to minimize any potential service interruptions and perform outreach to notify the community of potential service interruptions.

4.16 Historic and Archaeological Resources

4.16.1 Introduction to Resources and Regulatory Requirements

The National Historic Preservation Act of 1966 (NHPA) Section 106 states that any federal or federally assisted project or any project requiring federal licensing or permitting must consider the project's impacts on historic properties listed in or eligible for listing in the National Register of Historic Places (NRHP or National Register), in accordance with 36 CFR Part 800. Properties include historic and prehistoric archaeological sites, as well as districts, buildings, structures, objects, and landscapes, in addition to cultural or traditional places or resources that have value to a community, such as an Indian Tribal group (NHPA Section 101). To consider the potential concerns of Indian Tribes, Sound Transit also reviewed the following:

- American Indian Religious Freedom Act of 1978
- Executive Order (EO) 13007 (access to and/or ceremonial use of sacred sites by Indian religious practitioners)

Also, Section 4(f) of the Department of Transportation Act of 1966 (23 United State Code 138) prohibits the Federal Transit Administration (FTA) from approving a project or program that uses land from a significant public park, recreation area, wildlife or waterfowl refuge, or historic site, with the following exceptions:

- There is no feasible and prudent alternative to the use of the land.
- The project includes all possible planning to minimize harm to the property.

A Section 4(f) evaluation is included in Appendix D of this Final EIS.

The Cities of Seattle, Mercer Island, and Redmond regulate the impacts of projects on historic resources. The City of Bellevue has no applicable ordinances regarding historic resources.

Local regulations that were reviewed during the assessment include the following:

- City of Seattle Landmarks Preservation Ordinance (SMC 25.12) requires that properties eligible for city landmark designation be at least 25 years old and meet at least one of six criteria of significance.
- City of Mercer Island Ordinance No. 05C-09 (amending Ordinance No. 02-16) contains provisions for historic designation of private and municipal properties 50 years of age or older within the city limits.
- City of Redmond Ordinance No. 2224 contains provisions for historic preservation, including a Redmond Heritage Resource Register, administered by the Landmarks and Heritage Commission. Designation requires that a structure be at least 40 years of age and meet other criteria established by the Commission; archaeological sites also are eligible for designation.

Project historians and archaeologists analyzed 439 buildings or structures and investigated two archaeological sites. Of this total, 12 historic resources have been found to be listed in or eligible for listing in the NRHP. The Federal Transit Administration (FTA), in consultation with the State Historic Preservation Office (SHPO), has made a determination of adverse effect for the project. This determination results from the *preferred alternative's (B2M and C11A)* potential impacts on the Winters House and potential Surrey Downs historic district. Other alternatives would also impact the potential Surrey Downs Historic District and Justice White House.

A separately bounded Appendix H4, Historic and Archaeological Resources Technical Report, provides detail information on these historic resources.

4.16.2 Affected Environment

The FTA and Sound Transit consulted with the Washington State Historic Preservation Officer (SHPO) in the Department of Archaeology and Historic Preservation (DAHP), Washington State Department of Transportation (WSDOT), local jurisdictions, and Indian Tribes during the investigations concerning historic and archaeological resources. In addition, Sound Transit coordinated with staff at the Cities of Seattle, Mercer Island, Bellevue, and Redmond.

Sound Transit and FTA consulted with and received concurrence from DAHP on the Area of Potential Effects (APE) used for this project. The APE is the area within which the project may cause direct or indirect changes to the character of any historic properties. The APE for archaeological resources is limited to the portion of the project where ground-disturbing activities would be conducted, such as areas for demolition, construction, staging, equipment storage locations, and stormwater management facilities (36 CFR 800.16[d]). For the archaeological resource investigation, the vertical extent of the APE may vary according to construction practice—deeper for excavation areas and shallower for at-grade construction—and depending on the subsurface limits of known human use or occupation where the project feature occurs.

The APE for historical buildings and structures is one block (approximately 200 feet) on each side of the centerline of the project routes (i.e., a total corridor width of approximately 400 feet). The APE extends approximately 200 feet from the outer limits of station locations and maintenance facilities. The APE also includes the area one block from where tunnel alternatives could disturb the ground surface or potentially have other surface impacts, depending on terrain and local land use. Uniquely for bored or mined tunnel construction, the APE for noise, vibration, and settlement impacts is 100 feet on each side of the route centerline (i.e., a total corridor width of approximately 200 feet).

The archaeological sensitive areas and those listed or determined to be eligible historic resources within the study area's APE are shown in Exhibit 4.16-1. Detailed maps are available in the Historic and Archaeological Resources Technical Report (Appendix H4).

4.16.2.1 Archaeological Resources

Two archaeological sites have been recorded near the archaeological resource APE. Archaeological site 45KI8 was recorded in 1966 (Greengo, 1966) near the Redmond Way Alternative (E1). The site was described as consisting of scattered artifact finds along the east bank of the river for about one-half mile, including some finds in dredged material. The condition of the site in 1966 was reported as "completely worked over on surface—no midden [organic remains] visible" (Greengo, 1966).

Site 45KI 839 was recorded along lower Bear Creek, near the confluence of Bear Creek with the Sammamish River. The site is buried about 5 feet under the ground surface and consists of several stone tool fragments, stone flakes from tool-making, and fire-cracked rocks that appear to date to several thousand years old (Hodges et al., 2009).

Mapping of landform criteria for archaeological sensitivity identified several portions of the alternatives as having high sensitivity for prehistoric archaeological sites, but did not identify areas with a high sensitivity of important historic-period archaeological sites. The project archaeologist developed maps of areas judged to have high prehistoric archaeological sensitivity for the project alternatives based on historic stream courses, ethnographic land use, and topography of the terrain. These maps were compared with an archaeological model prepared for the DAHP.

Archaeological sensitivity and survey maps are provided in Appendix H4. Much of the Segment B and E alternatives have relatively high levels of archaeological sensitivity based on the presence of Mercer Slough in Segment B and the Sammamish River floodplain in Segment E.

Also shown in Appendix H4 are the survey tracts with shovel test probe locations that were excavated during the archaeological survey. A field crew conducted an archaeological survey for the 2008 Draft EIS in February 2007 and for the Final EIS (Stage 1) in March, June, and July 2010 (Thompson and Gilpin, 2010). The work included 27 survey tracts placed primarily in archaeologically sensitive areas but also included low-sensitivity areas. The survey placed 12 tracts in the archaeologically sensitive portions of Segment B, 7 in Segment D which varied as both low and medium archaeologically sensitive, and 8 in the archaeologically sensitive portions of Segment E. Two survey tracts (in Segment D) were placed in areas considered to have low archaeological sensitivity to control for the bias inherent in focusing surveys on high-sensitivity areas. No tracts were placed in Segments A or C because heavy development and other characteristics provided relatively fewer areas of high archaeological sensitivity. One of the Draft EIS survey tracts and two of the Final EIS survey tracts were unable to be surveyed due to issues with entry and/or significant surface disturbances. A preconstruction archaeological survey will provide additional information and guidance for uncovering historic resources during construction.

The archaeological survey of the Segment B tracts encountered areas of historical disturbance, heavy vegetation, water near or at the ground surface, and modern debris. Survey tracts in Segment D also showed considerable disturbance, while many of those in Segment E (particularly along the Sammamish River) encountered fill covering the native soils up to about 3 feet deep. The project archaeologist identified an additional survey tract to search for recorded archaeological site 45KI8 described above, but encountered no evidence of the site. It is difficult to tell whether the site still exists because the area has been eroded, dredged, rip-rapped, and filled.

Exhibit 4.16-1

Cultural Resources

Segments A, B, C, D, and E

East Link Project

None of the surveys located prehistoric archaeological remains. One historic-period archaeological site was recorded during the 2010 survey session. This site consisted of a scatter of domestic debris found in a survey tract along Segment B. The site is not eligible for listing in the NRHP because it did not retain many aspects of integrity nor did it meet any of the four criteria for listing.

In summary, the survey located no NRHP-eligible prehistoric or historic-period archaeological remains at archaeological site 45KI8. These results are not conclusive because buried materials and sites could be found, particularly along the Segment B and Segment E alternatives. Although past development has likely damaged or destroyed archaeological sites, some important remains could exist.

4.16.2.2 Traditional Cultural Properties

FTA and Sound Transit have conducted government-to-government consultation with the Muckleshoot Indian Tribe, Snoqualmie Indian Tribe, Suquamish Tribe, Duwamish Tribe, Tulalip Tribes of Washington, and Yakama Nation, initially providing project information by mail. Meetings have been held with Snoqualmie and Muckleshoot Tribal representatives to discuss the project and its potential impacts on archaeological sites and traditional cultural properties (TCPs). Consultation with the Tribes has revealed no traditional cultural properties in the project vicinity.

4.16.2.3 Historic Buildings and Structures

A historical records search was performed that identified several properties listed in the National Register, the Washington Heritage Register (WHR), or local registers. Appendix H4 lists the properties inventoried and shows the properties determined to meet the National Register and local ordinance criteria by 2016. Inventoried resources would be 50 years old by the baseline year 2016. Field surveys by project historians and preparation of inventory forms took place primarily from February through June 2007, September through October 2007, and February to April 2010. The field surveys inventoried 439 buildings and structures (including one potential historic district) in the APE, with 12 either listed in the National Register (and thus automatically listed in the WHR) or recommended to be eligible. Sound Transit also conducted field tours with DAHP staff to identify properties that appeared to meet National Register eligibility criteria.

The DAHP reviews NRHP recommendations for concurrence, and the local jurisdictions review local landmark register recommendations. Letters from the DAHP and local jurisdictions concurring on the eligibility of the historic properties can be found in Appendix H4. Table 4.16-1 summarizes the NRHP- or local-listed or eligible properties identified in the APE, Exhibits 4.16-2 through 4.16-11 and 4.16-12 through 4.16-17 are photographs of these properties, and the following subsections discuss these properties.

In addition to resources discussed in the remainder of this section, one potential historic resource, the former BNSF Railway, was surveyed in the APE for multiple project segments. Portions of the former BNSF Railway are within the APE for Segments B, C, D, and E. The portions of the former BNSF Railway within the project’s APE have been determined as not eligible for listing in the NRHP, although the railroad as a whole has been determined eligible from a previous archaeological investigation. These portions are nondescript and do not well represent the theme of the railroad as a whole. Significant intact properties representative of the former BNSF Railway's and the preceding owners’ contributions to railroad technology are not presented by portions of the former BNSF Railway in these segments of the project corridor.

Segment A

The five historic structures and buildings in Segment A are on the NRHP and have already been recorded at the Washington DAHP. They are the Publix Hotel, located within the Seattle Chinatown National Register Historic District and the International Special Review Historic District; the Immigrant Station and Assay Office Building (INS Building); the Jose Rizal 12th Avenue South Bridge; the Will H. Thompson House; and the Mount Baker Ridge Tunnels and Eastern Portals. In addition, WSDOT, on behalf of the Federal Highway Administration and DAHP, identified a segment of I-90 between I-5 and I-405, which includes the Mount Baker Ridge Tunnels and Eastern Portals, as eligible for the NRHP and therefore nominated these as one eligible resource. DAHP concurred with this determination in a letter dated November 23, 2009.

The architecture of the INS Building features Neo-classical and Mediterranean elements, as shown in Exhibit 4.16-2. The building is important for its role in history, particularly that of Asian immigration. The Publix Hotel in the Seattle Chinatown NRHP Historic

SL	Seattle Landmark
RHL	Redmond Historic Landmark
WHR	Washington Heritage Register

District is significant for its association with Seattle history (Exhibit 4.16-3). The 12th Avenue South Bridge, constructed in 1911, was listed in the NRHP based on its engineering design (Exhibit 4.16-4). The Mount Baker Tunnels' architects designed an impressive gateway to the City of Seattle by combining Art Deco elements and stylized Native American motifs, as shown in Exhibit 4.16-5. Although the tunnels were an engineering feat, the National Register listing focuses on their striking ornamentation.

The Lake Washington Segment of I-90 between Martin Luther King Jr. Way in Seattle and East Channel Bridge in Bellevue was determined eligible for the NRHP as a key piece of transportation history. It included extensive community involvement and design of the centerlanes for transit (Exhibit 4.16-6). It is also significant for its innovative engineering and design that incorporated floating bridges, landscaped lids, and minimized community impacts. Although the facility is less than 50 years old, it qualified for listing in the NRHP under Criteria Consideration G, achieving significance because of its exceptional importance. The Will H. Thompson House is significant due to its architecture and high level of integrity (Exhibit 4.16-7).

In addition, City of Seattle has determined that the Endresen Residence at 1402 32nd Avenue (Exhibit 4.16-8) and the Romaine Electric/Washington Iron Works building at 1101 Airport Way (Exhibit 4.16-9) may be eligible for City Landmark status. However, these buildings were determined not eligible for the NRHP.

Segment B

The Winters House was listed in the NRHP in 1992 based on its Spanish Eclectic architecture, as shown in Exhibit 4.16-10, and its association with the bulb-growing and floriculture industry in King County and Washington. The Winters House is currently used by the Eastside Heritage Center as a heritage research center, exhibit space, archive storage, library, and public meeting space. Additionally, the Eastside Heritage Center provides public and educational programming at the Winters House. The Winters House also contains office space for the City of Bellevue Parks and Community Service Department staff and can be used for public or private meeting event space. The Winters House is part of the Heritage Loop Trail in Mercer Slough Nature Park; the site includes historical interpretation and facilities for trail users. The Pilgrim Lutheran Church (Exhibit 4.16-11), completed in 1965, is an outstanding example of Neo-Expressionist architectural style. The firm that designed the building—Grant, Copeland, Chervenak and Associates—won awards for several of their local projects.

Segment C

A portion of the Surrey Downs residential subdivision is potentially eligible for the NRHP as a historic district (see Exhibit 4.16-18). According to discussions with DAHP, this residential area has not been determined eligible because many of the houses in the Surrey Downs neighborhood are outside the Area of Potential Effect and thus were not analyzed for historic significance. A district is a concentration of buildings or other properties that may or may not be individually eligible for the National Register, but are linked by one or more features that define their character. To be considered eligible as part of the potential Surrey Downs historic district, the houses need to be a consistent architectural style and not have been outwardly modified since their construction. The district is unique because the subdivision featured home designs that are of the post-World-War II called "Northwest Modern" Style of design created by Mithun & Nesland, a Seattle architectural firm. The DAHP determined 37 houses would be contributing elements to the potential historic district within the project APE. The historians did not establish boundaries for the district because it extends beyond the project APE. The house in Exhibit 4.16-12 is representative of the Northwest Modern style of design (18 houses in the potential historic district), which includes one-story houses with carports and two-story houses with garages located beneath the living space. Other contributing houses include split-level (11 houses) and ranch (8 houses) styles. Exhibit 4.16-18 shows the location of each of the contributing homes within the APE, and the properties are listed in Appendix H4.

Facing Bellevue Way NE just north of NE 4th Street, the currently closed Safeway store built in 1962 is eligible for the NRHP based on its distinctive character of a large-scale commercial grocery store of the 1960s era (Exhibit 4.16-13).

Segment D

One NRHP-eligible structure was identified in Segment D. The Former Bellevue Fire Station on Bel-Red Road, constructed in 1960, is a good example of Populuxe architecture, a style reminiscent of 1950s aerodynamic design (Exhibit 4.16-14).

Segment E

The Justice William White House (Exhibit 4.16-15) and the Bill Brown Saloon Building (Exhibit 4.16-16) are designated as Redmond Heritage Landmarks and are also eligible for listing in the NRHP (and therefore also for the WHR). The Justice William White House is important because its owners, William and Emma McRedmond White, both played important roles in the history of Redmond and western Washington. They set aside a part of the house, which was built in 1900, as a hotel because it was conveniently located close to the railroad line and the passenger depot, giving guests easy access.

The Redmond Trading Company building, currently occupied by Half Price Books, is a City of Redmond Heritage Landmark. This building was built in 1910 to house the trading company that was Redmond's largest business for decades. This building is not considered eligible for listing in the NRHP or the WHR since the display windows along the Leary Way side of the building is the only remaining characteristic from the original façade.

The Bill Brown Saloon Building is important because of its association with the man who was mayor of Redmond from 1919 to 1948. Beginning about 1915, the building's second floor served as an unofficial Redmond City Hall (Hardy, 2001).

The Dudley Carter/Haida House is a City of Redmond Heritage Landmark, and the City considers it to be eligible for listing in the National Register (Exhibit 4.16-17). It was constructed by nationally known, Canadian-born artist Dudley Carter following methods of the Haida First Nation. Review conducted by DAHP, however, determined that because the building is less than 50 years old and not of exceptional significance, it does not qualify for the National Register.

4.16.3 Environmental Impacts

4.16.3.1 Impact Evaluation Methods

The Advisory Council on Historic Preservation's regulations implementing NHPA Section 106 create a process by which federally assisted projects are reviewed for their effects on properties listed in, or eligible for listing in, the NRHP.

After the resource is identified and evaluated, the next step is applying the Criteria of Adverse Effect. These criteria are used to determine whether the undertaking could change the characteristics that qualify the property for NRHP inclusion. An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Adverse effects include, but are not limited to, the following:

- Demolition or alteration of the property
- Alteration of the property's setting
- Introduction of visual, audible, or atmospheric elements that are out of character with the setting of the historic property

EXHIBIT 4.16-18
Contributing Properties to the Potential Surrey Downs Historic District

- Physical encroachment upon an archaeological site.
- Pursuant to 36CFR Part 800.5(b), an agency may propose a finding of no adverse effect in consultation with the SHPO when the undertaking is modified or conditions are imposed to avoid adverse effects.

FTA, in consultation with SHPO, has made a determination of adverse effect for the project. This determination results from the project's potential impacts on the Winters House by *Preferred Alternative B2M* and on the potential Surrey Downs Historic District by *Preferred Alternative C11A*, and Alternatives C4A, C2T and C3T. The Justice William White House would be potentially impacted by Alternative E4 because it would require relocation. Minimization and mitigation measures have been developed to resolve the potential impacts on these resources. The project would not adversely impact the other historic resources.

4.16.3.2 No Build Alternative

The No Build Alternative would not affect any historic properties.

4.16.3.3 Impacts during Operation

Although some potentially sensitive archaeological areas are identified, studies to date have identified no NRHP-eligible prehistoric or historic-period archaeological sites in the project APE. If one or more archaeological sites were identified in future studies, evaluation and treatment would be completed. The following subsections discuss the potential effects of project operation on historic buildings and structures.

Segment A

Operation of the light rail system with *Preferred Interstate 90 Alternative (A1)* is not anticipated to affect the eight historic properties identified in Table 4.16-1 because of the position of *Preferred Alternative A1* in the center of I-90.

The Publix Hotel is across the street to the east from the International District Station entrance, and the project would not result in aboveground changes in the immediate vicinity. The INS Building is situated at the Fifth Avenue S/I-90 ramp, and the light rail facility would be under Airport Way and not visible near this building. Due to the location of the project alternative in the existing D2 Roadway right-of-way and the project's consistency with the transit function and appearance of this facility, operation of the project would similarly not adversely impact the Romaine Electric/Washington Iron Works Pattern Shop structure or setting. The operation of the project along I-90 at-grade beneath the 12th Avenue South Bridge would not adversely impact the setting of the bridge because the project is within the boundaries of the existing I-90 roadway.

The Will H. Thompson House would not have vibration or impacts from this project. Due to the distance of *Preferred Alternative A1* from the residence at 1402 32nd Avenue South and the project's location in a tunnel within the existing I-90 right-of-way, operation of the project along I-90 at-grade would not adversely impact this historic property.

Preferred Alternative A1 would be constructed within I-90's existing center roadway and would not require widening of the facility (Exhibit 4.16-19) within Segment A. The design, materials, and workmanship of the tunnels, portals, floating bridges, and lids would not substantially change. The structural integrity and intended use of the facility would be maintained. *Preferred Alternative A1* is consistent with the historical aspects, features, and characteristics of this segment of I-90 and the bridge's long-term planning objectives and would not diminish the resource as a key piece of transportation history with innovative engineering and planning for future rail transit. Due to the context of I-90 as a transportation corridor, with early planning for rail transit, and the East Link project's location in the center roadway, the project would not change the character-defining features that qualify the resource to be included in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. In conclusion, none of the historic buildings and structures in Segment A would be impacted by the project during operations.

Segment B

Preferred 112th SE Modified Alternative (B2M) is proposed to be located within the 50-foot boundary established in the Winters House NRHP nomination form. *Preferred Alternative B2M* passes directly in front of the Winters House in a lidded retained cut. The eastern edge of the *Preferred Alternative B2M* right-of-way measures approximately 10 feet from building foundation and 5 feet from the edge of the Winters House porch but is located in a lidded retained cut that is completely below grade.

I-90 Floating Bridges with Visual Simulation of Light Rail in Center Roadway

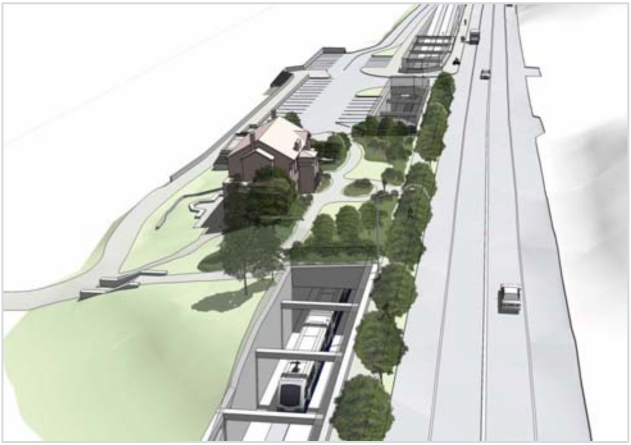

EXHIBIT 4.16-20
Winters House, *Preferred Alternative B2M* Birds' Eye View

Exhibit 4.16-20 depicts the Winters House with the proposed project (*Preferred Alternative B2M*), and Exhibit 4.16-21 shows the existing cross-section as well as the cross-section for *B2M*. The perspective and cross-section views illustrate minimization approaches incorporated into the project design to maintain historic integrity during light rail operation.

EXHIBIT 4.16-21
Cross Section of *Preferred Alternative B2M* Adjacent to Winters House

These elements include placing the light rail in a 170-foot-long lidded retained cut that would extend the width of the house and the length of the 50-foot property boundary on each side of the house, as identified in the NRHP nomination. Landscaping sensitive to the historic nature of the building and setting would be installed. Additional impacts on the Winters House property include a required American with Disabilities Act (ADA)-accessible ramp to connect the building to the parking lot; the sidewalk (per the City of Bellevue's requirement), which encroaches onto the front lawn by 5 feet; and a load restriction over the lidded trench that prohibits vehicles from driving on the front lawn, thus requiring deliveries at the first level of the building. Adjacent parking, which is located outside of the 50 feet nomination boundary, would be replaced with a new parking structure.

Whereas the Winters House would continue to fully convey its significance as outlined in its NRHP registration form, the 50-foot boundary around the house has been reduced by the widening of Bellevue Way SE, and the landscaping within this area no longer retain integrity because of several changes to the area over time.
